\textbf{Abstract}
Sugeno integrals and their particular cases such as weighted minimum and maximum have been used in multiple-criteria aggregation when the evaluation scale is qualitative. This paper proposes two new variants of weighted minimum and maximum, where the criteria weights play the role of tolerance thresholds. These variants require the use of a residuated structure, equipped with an involutive negation. We propose residuated counterparts of Sugeno integrals, where the weights bear on subsets of criteria, and we study their properties, showing they are analogous to Sugeno integrals to a large extent. Finally we propose dual aggregation operations, we call desintegrals, where an item is evaluated in terms of its defects rather than in terms of its positive features. Desintegrals are maximal when no defects at all are present, while integrals are maximal when all merits are sufficiently present. Qualitative integrals and desintegrals suggest a possible approach to bipolar evaluation processes where items are judged both in terms of merits and defects that are not independent of one another.

\section{1. Introduction}

In multiple-criteria decision making, Sugeno integrals are commonly used as qualitative aggregation functions \cite{30}. They are qualitative counterparts to quantitative Choquet integrals, and only require an ordered setting. Especially, like a Choquet integral, Sugeno integral delivers a score between the minimum and the maximum of the aggregated partial ratings. The definitions of Sugeno and Choquet integrals are both based on a monotonic set-function named capacity \cite{3} or fuzzy measure \cite{38}. These set functions are basic tools that can be encountered in many areas, in particular in uncertainty modelling \cite{23}, multiple criteria aggregation \cite{27,30}, group decision \cite{32} and game theory \cite{37}. They are used to represent the importance of the sets of possible states of nature, sets of criteria, groups of decision makers, etc. If the range of the capacity is considered as a finite totally ordered scale, then the capacity is said to be qualitative, or a $q$-capacity for short (it includes numerical scales provided that addition is not used).

In multiple-criteria analysis, the importance of the criteria can be exploited in different ways when aggregating partial evaluations. In weighted averages, the weights are like a number of allowed repetitions of a criterion (everything goes as if the value of an important criterion appears more times than the value of a less important one in the additive aggregation process). In Sugeno integrals, they are just thresholds that restrict the global satisfaction from below or from above. In this paper we consider variants of Sugeno integrals where the importance level is considered as a tolerance threshold such that passing it is sufficient to
obtain the best rating, or a minimal requirement threshold that, if not reached, leads to modifying the original evaluation in some appropriate way. These variants, we call qualitative integrals, use an evaluation scale that is a both a totally ordered Heyting algebra and a Kleene algebra: a finite chain equipped with a residuated implication and an involutive negation [18]. In the recent past, Dvorák and Holčapek [24,25] also studied residuated variants of Sugeno integral, however in the MV-algebra setting, which is no longer qualitative. Our framework is less expressive.

Besides we also focus on the polarity of the evaluation scale. It is worth noticing that when Sugeno integral or these variants are used, the criteria have a positive flavour: the higher their values, the better the corresponding evaluation. But sometimes local ratings only reflect the gravity of defects, and the global evaluation decreases when the partial ratings increase. Such kinds of criteria are said to be negative. In such a case other variants of the Sugeno integrals, we call qualitative desintegrals, can be defined. With these new aggregation functions, the more a negative criterion is satisfied, the worse is the global evaluation (that we shall always assume to lie in a positive scale). In the definition of desintegrals, capacities are then replaced by fuzzy anti-measures, which are decreasing set functions. They are used to represent a tolerance or a permissiveness level on the negative scales. Similarly to qualitative integrals, such importance levels can be exploited in different ways when aggregating partial evaluations, which induce as many variants of qualitative desintegrals as there are qualitative integrals.

Finally, we exploit the fact that, in a finite setting, a capacity can be represented by a family of possibility distributions, as it is the lower (resp. upper) bound of the corresponding possibility (resp. necessity) measures [1,5,20,21], and a Sugeno integral is a lower (resp. upper) bound of qualitative integrals with respect to such possibility (resp. necessity) measures, or equivalently lower bounds on prioritised maxima (resp. upper bounds on prioritised minima) [5,21]. Dually, decreasing set functions can also be represented in terms of decreasing max- or min-decomposable measures. These properties entail a natural question: could we express general qualitative integrals (resp. desintegrals) in terms of the maximum or minimum of finite families of simpler integrals (resp. desintegrals) of the same type with respect to possibility or necessity (resp. guaranteed possibility and weak necessity) measures. This paper addresses this question as well. A positive answer means that in a number of cases the complexity of calculating a qualitative integral can be significantly reduced.

The paper is structured as follows. Section 2 presents the algebraic framework needed in the paper. Section 3 describes two new variants of weighted minimum and maximum. Section 4 presents their extensions in the form of residuation-based variants of Sugeno integrals and studies some of their properties. Section 5 is devoted to the negative counterparts of qualitative integrals, when local evaluations belong to negative scales.

2. Algebraic framework

In this section we first recall the qualitative setting of totally ordered Heyting algebras used as rating scales in multifactorial evaluation.

We consider a finite set of criteria \( C = \{1, \ldots, n\} \). The objects considered are evaluated using these criteria. The evaluation scale, \( L \), associated with each criterion is assumed to be a totally ordered set. It may be finite or be the interval \([0, 1]\). In both cases, the bottom is denoted by 0 and the top is denoted by 1. The maximum (resp. minimum) will be denoted by \( \lor \) (resp. \( \land \)). An object is represented by a vector of ratings on the different criteria, i.e., by \( f = (f_1, \ldots, f_n) \in L^n \) where \( f_i \) is the rating of \( f \) according to the criterion \( i \). In other words, an object is viewed as a function \( f \) from \( C \) to \( L \). In the following, without loss of generality when we consider an object \( f \) we suppose that \( f_1 \leq \cdots \leq f_n \) (we can consider a suitable permutation on the set of criteria determined by the \( f_i \)'s), and we denote by \( A_i \) the set of indices \( \{i, \ldots, n\} \) with the convention \( A_{n+1} = \emptyset \).

Moreover, on \( L \) we can define Gödel implication \( \rightarrow_c \) using the residuation \( \text{Res} \) as follows

\[
a \land b \leq c \Leftrightarrow a \leq b \rightarrow_c c.
\]

so that \( b \rightarrow_c c \equiv \lor \{a : a \land b \leq c\} \) that we denote by \( b \text{Res} \land c \). In such a context \( (L, \land, \lor, 0, 1, \rightarrow_c) \) is a special case of Heyting algebra, i.e., a special case of complete residuated lattice; indeed \( (L, \land, \lor, 0, 1) \) is a chain and \( (L, \land, 1) \) is a commutative monoid (since \( \land \) is associative, commutative and for all \( a \in L \), \( a \land 1 = a \)).

In the following, we will consider positive criteria and negative criteria. In order to handle the polarity of the evaluation scale, we also need an order-reversing operation on \( L \), denoted by \( 1 \rightleftharpoons \), that is decreasing and involutive (a Kleene negation, since the structure \( (L, \land, \lor, 0, 1, 1 \rightleftharpoons) \) is a Kleene algebra). In this paper \( L \) is either a positive scale (1 means good, 0 means neutral), or a negative scale (1 means bad, 0 means neutral). On a complete residuated lattice (with residuated implication denoted by \( \rightarrow \)), another negation is defined by \( \neg a = a \rightarrow 0 \) such that \( \neg a = 1 \) if \( a = 0 \) and 0 otherwise, hence not involutive. This negation clearly differs from the Kleene negation.

In the structure \( (L, \land, \lor, 0, 1, 1 \rightleftharpoons) \) there are thus at least three different implications we are going to use in this paper:

- the Gödel implication defined by \( a \rightarrow_c b = 1 \) if \( a \leq b \) and \( b \) otherwise;
- the Kleene–Dienes implication: \( a \rightarrow_D b = (1 \rightleftharpoons a) \lor b; \)
- the contrapositive Gödel implication \( \rightarrow_{\neg c} = \neg c \rightarrow_c : a \rightarrow_{\neg c} b = (1 \rightleftharpoons b) \rightarrow_c (1 \rightleftharpoons a) \) if \( a \leq b \) and \( 1 \rightleftharpoons a \) otherwise.

The contraposition \( \neg c \) applies to any binary operation \( \sqcup \) in a Kleene algebra, and is such that \( a\neg c \sqcup b = (1 \rightleftharpoons b) \sqcup (1 \rightleftharpoons a) \).

Likewise, to each implication \( \rightarrow \) can be associated a conjunction \( \ast = S( \rightarrow ) \) defined by

\[
a \ast b = 1 - (a \rightarrow (1 \rightleftharpoons b)).
\]

Transformation \( S \) is already considered in [10]. Via this transformation, one obtains three conjunctions, two of which are non-commutative:
3.1. Saturation levels

Conjunctions
do not induce

Moreover in [10] it was proved that the generation process of conjunctions modelled by the triangular norm & is closed as represented in Fig. 1, where Res( ⋅ ) is the residuated operation Res( ⋅ ) ∈ a∧b ≤ c. Also, ⋅ = S( → ) is equivalent to →⇒ S( * ).

Remark 1. Note that the operation a ⋅ b = (a ∨ b) ⋆ (a ⋆ b) = a ∧ b if a > 1 − b, and 0 otherwise, is yet another conjunction known as the nilpotent minimum [26,36]. The corresponding residuated implication is defined by a → ⋅ b = 1 if a ≤ b and a → ⋅ b otherwise (it is [a → ⋅ b] ⋆ (a → ⋅ b)). This implication is clearly self-contrapositive (a → ⋅ b = (1 − b) ⋆ (1 − a)), and such that S( ⋅ ) =⇒ . So there are more implications in the considered structure than the three ones we consider in this paper. However we shall not use → ⋅ here and leave it for further research.

3. Simple qualitative aggregation schemes on positive scales

This section focuses on the possible elementary qualitative aggregation functions when we consider positive criteria. In such a context the local scales and the global scale are positive.

There are two elementary qualitative aggregation schemes:

- The first one, ∧(i=1..n) fi is pessimistic and very demanding; namely, in order to obtain a good global evaluation, an object needs to satisfy all the criteria.
- The second one, ∨(i=1..n) fi is optimistic and very loose; namely, one fulfilled criterion is enough to obtain a good global evaluation.

These two aggregation schemes can be generalised by means of importance levels or priorities πi ∈ L, on the criteria i, i = 1, . . . , n as recalled below. Suppose πi is all the greater as the criterion i is important. A fully important criterion has importance weight πi = 1. In the following, we assume πi > 0, ∀i, i.e., there is no useless criterion. In this section, we also assume πi = 1, for some criterion i (the most important one). These importance levels can alter each local evaluation fi in different manners. More precisely, πi can act as a saturation threshold that blocks the global score under or above a certain value dependent on the importance level of criterion i. Alternatively, πi can be considered as a threshold above which the decision-maker is perfectly satisfied and under which the local rating is altered or not. There are two such rating modification schemes (already discussed, e.g., in [16] for the handling of some kinds of queries in fuzzy relational databases). All of them use a pair (implication, conjunction) defined previously. Let us present all these cases in details.

3.1. Saturation levels

Here the importance weights act as saturation levels; they reduce the evaluation scale from above or from below. The rating fi is modified either into (1 − πi) ⋆ fi ∈ [1 − πi, 1], or πi ⋆ fi ∈ [0, πi]. Only a fully important criterion can range on the whole global score scale.

- In a demanding aggregation, all the important criteria have to be satisfied, which justifies the prioritised minimum [11,41]:

\[
SLMIN_\pi (f) = \bigwedge_{i=1}^n (1 - \pi_i) \vee f_i = \bigwedge_{i=1}^n \pi_i \rightarrow f_i.
\]

Hence an important criterion can alone bring the overall score very low and a criterion that is of little importance cannot downgrade the overall score under a certain level 1 - πi. A fully important criterion (πi = 1) acts as a veto as it can lead to a zero global score if violated. This is why under this aggregation scheme, such criteria can actually be viewed as soft constraints [8]. The weights πi are priorities, that affect the level of acceptance of objects that violate criteria.

![Diagram](image-url)
• In a loose aggregation, we just need to satisfy one important criterion, which justifies the prioritised maximum [11,40]:

\[
S_{\text{MAX}}(f) = \bigvee_{i=1}^{n} \pi_i \land f_i = \bigvee_{i=1}^{n} \pi_i \ast_G f_i.
\]

In this case an important criterion is one that alone can bring a good overall score (a maximal one for a fully important criterion) and a not important criterion can never alone bring the overall score higher than \(\pi_i\).

It is well-known [11] that if the evaluation scale of the local ratings \(f_i\) is reduced to \(\{0, 1\}\) (Boolean criteria) then letting \(A_f = \{i : f_i = 1\}\) be the set of criteria satisfied by object \(f\). \(S_{\text{MAX}}(f) = \bigvee\{\pi_i : i \in A_f\}\) is a possibility measure [42] (a maxitive capacity), and \(S_{\text{MIN}}(f) = \bigwedge\{1 - \pi_i : i \notin A_f\}\) is a necessity measure [12] (a minitive capacity). Obviously, \(S_{\text{MIN}}(f)\) is minitive, namely

\[
S_{\text{MIN}}(f \land g) = \min(S_{\text{MIN}}(f), S_{\text{MIN}}(g)),
\]
and \(S_{\text{MAX}}(f)\) is maxitive, namely

\[
S_{\text{MAX}}(f \lor g) = \max(S_{\text{MAX}}(f), S_{\text{MAX}}(g)).
\]

Note that we have the following De Morgan-like property, that extends the well-known duality \(\Pi(A) = 1 - N(A)\), where \(\overline{A}\) is the complement of \(A\), to graded tuples \(f\):

\[
S_{\text{MAX}}(f) = 1 - S_{\text{MIN}}(1 - f).
\]

3.2. Softening thresholds

The importance weight \(\pi_i\) of a criterion can be considered as an excellence threshold that, if passed by the corresponding local rating of an object, is sufficient to result in full local satisfaction for this object. Namely, if \(f_i \geq 1 - \pi_i\), then the local rating becomes maximal, i.e. 1. Otherwise, if \(f_i \leq 1 - \pi_i\) then the local rating remains as it stands. Clearly, the effect of the weight \(\pi_i\) on the original local rating \(f_i\) is to turn it into \(\pi_i \rightarrow c f_i\).

• The demanding aggregation is obtained replacing \(\rightarrow\) by \(\rightarrow\). We get

\[
S_{\text{MIN}}(f) = \bigwedge_{i=1}^{n} \pi_i \rightarrow_G f_i.
\]

The idea is still that the evaluated item should get good grades for all important criteria. In this case, a criterion is all the less important as the required rating for considering it fulfilled is low. A fully important criterion is considered satisfied only if \(f_i = 1\). A criterion \(i\) with a low importance weight \(\pi_i\) is satisfied even by objects for which \(f_i\) is low, provided that this local rating is above \(\pi_i\). Note that \(S_{\text{MIN}}(f)\) is minitive, namely \(S_{\text{MIN}}(f \land g) = \min(S_{\text{MIN}}(f), S_{\text{MIN}}(g))\).

• We can define the corresponding loose aggregation, changing \(\land\) into the conjunction \(\ast_G\) associated with \(\rightarrow\) in the SMAX aggregation scheme:

\[
S_{\text{MAX}}(f) = \bigvee_{i=1}^{n} \pi_i \ast_G f_i.
\]

Since \(\pi_i \ast_G f_i \geq 0\) as soon as \(f_i \leq 1 - \pi_i\), it means that for a little important criterion, the local rating for criterion \(i\) must be very high (at least \(1 - \pi_i\)) to influence the global score and it is eliminated otherwise. On the contrary, an important criterion \(i\) may affect the global rating even if the corresponding local rating is low. Note that \(S_{\text{MAX}}(f)\) is maxitive, namely \(S_{\text{MAX}}(f \lor g) = \max(S_{\text{MAX}}(f), S_{\text{MAX}}(g))\).

These aggregation schemes are better understood if written as:

\[
S_{\text{MIN}}(f) = \bigwedge_{i : f_i < \pi_i} f_i; \quad S_{\text{MAX}}(f) = \bigvee_{i : f_i > 1 - \pi_i} f_i
\]

with the usual conventions \(\bigwedge \emptyset = 1; \bigvee \emptyset = 0\). For instance, in the academic context, a student contest will select on an equal basis all students having sufficiently good marks in the various academic disciplines (they are all considered equally successful), and the unsuccessful ones can still be rank-ordered according to their worst (insufficient) marks. This is modelled by the soft implication-based demanding aggregation \(S_{\text{MIN}}(f)\). In contrast, the loose aggregation (5) eliminates candidates that failed in all disciplines, getting marks less than the thresholds \(1 - \pi_i\), and will rank-order the other students according to their best marks.

It is easy to see that

• \(S_{\text{MIN}}(f) = 1\) if and only if \(f_i \geq \pi_i, \forall i = 1, \ldots, n\), that is if and only if the local ratings reach at least the levels prescribed by the importance thresholds. Note that it is a rather unsurprising demand.

• \(S_{\text{MIN}}(f) = 0\) if and only if \(\exists i, f_i = 0\) and \(\pi_i > 0\), that is if some criterion is totally violated.

1 The latter condition is assumed for all criteria.
• STMAX_π(f) = 1 if and only if ∃i, f_i = 1 and π_i > 0, that is if some criterion is totally satisfied.
• STMAX_π(f) = 0 if and only if ∀i, f_i ≤ 1 − π_i, that is if no criterion passes the rating threshold 1 − π_i.

In fact, with STMIN_π(f), the weights select violated criteria that alone are enough to eliminate f, and with STMAX_π(f), the weights select satisfied criteria that alone are enough to accept f.

We have again the following De Morgan-like duality:

\[ STMAX_\pi(f) = 1 - STMIN_\pi(1 - f). \]  

However, STMIN_π(f) and STMAX_π(f) cannot be considered as a proper generalisation to fuzzy events of possibility and necessity measures, since when the f_i’s belong to {0, 1} so that f corresponds to the characteristic function a set A_f, we do not get STMIN_π(f) = N(A_f) nor STMAX_π(f) = Π(A_f).

Indeed, in that case STMIN_π(f) ∈ {0, 1} and STMAX_π(f) ∈ {0, 1} as well. Namely STMIN_π(f) = 1 if A_f = C. 0 otherwise, and STMAX_π(f) = 1 if A_f ≠ ∅, 0 otherwise. In other words, everything happens as if weights were all equal to 1, STMIN_π being a standard conjunction, and STMAX_π a standard disjunction. It is known [15] that the residuation-based extension of necessity measures to fuzzy events is not based on Gödel implication, but on its contrapositive form.

3.3. Drastic thresholds

Another way of handling importance weights is to downgrade or upgrade local ratings to a fixed value when they fail to reach the importance thresholds π_i, this prescribed value being all the lower as the criterion is important. Namely, if f_i < π_i then we set the rating to 1 − π_i. As a consequence, the modified rating is modelled by π_i ↩ cDf_i, so that the local evaluation scale of criterion i is reduced to binary values in the set {1 − π_i, 1}, which is a drastic way of handling graded ratings. Again we shall have demanding and loose aggregations.

• The demanding aggregation will be

\[ DTMIN_\pi(f) = \bigwedge_{i=1}^n \pi_i \rightarrow_{GC} f_i. \]  

When violated (i.e. the threshold π_i is missed), an important criterion alone may drastically downgrade the overall score, while the local rating according to an unimportant criterion may be upgraded (in each case, to 1 − π_i, which is low in the first case and high in the second case). Note that DTMIN_π is minitive, namely DTMIN_π(f ∧ g) = min(DTMIN_π(f), DTMIN_π(g)).

• The loose counterpart will be

\[ DTMAX_\pi(f) = \bigvee_{i=1}^n \pi_i \leftarrow_{GC} f_i. \]  

An important criterion, if satisfied, can alone bring the overall score to a high value but an unimportant criterion, even if satisfied, cannot bring the overall score to a high value (π_i in each case). DTMAX_π is maxitive, namely DTMAX_π(f ∨ g) = max(DTMAX_π(f), DTMAX_π(g)).

These aggregation schemes are better understood if expressed as follows:

\[ DTMIN_\pi(f) = \bigwedge_{i: f_i \leq \pi_i} 1 - \pi_i; \quad DTMAX_\pi(f) = \bigvee_{i: f_i > 1 - \pi_i} \pi_i. \]  

Letting A^↓_f = \{i: f_i ≥ \pi_i\}, we observe that DTMIN_π(f) = N(A^↓_f). Likewise denoting A^↑_f = \{i: f_i > 1 - \pi_i\}, we observe that DTMAX_π(f) = Π(A^↑_f). When f_i ∈ {0, 1}, and A_f = \{i: f_i = 1\}, we do get necessity and possibility measures (DTMIN_π(f) = N(A^↓_f)) = N(A_f). DTMAX_π(f) = Π(A^↑_f) = Π(A_f), where A^↓_f = A^↓_f \uplus \{i: \pi_i > 0\}. We have again the expected duality property:

\[ DTMAX_\pi(f) = 1 - DTMIN_\pi(1 - f). \]  

Remark 2. There are alternative ways of handling importance weights in the qualitative setting. In the scope of a loose aggregation, one way would be to downgrade to 0 ratings that do not pass the importance threshold π_i, keeping them as such otherwise. This operation is a kind of residuated subtraction f_i ⊙ π_i = inf\{x: π_i ∨ x ≥ f_i\} = f_i if π_i < f_i and 0 otherwise.

It would lead to consider aggregation schemes of the form:

\[ SUMAX_\pi(f) = \bigvee_{i: f_i < \pi_i} f_i; \quad SUMIN_\pi(f) = \bigwedge_{i: f_i > 1 - \pi_i} f_i \]

The last equation is obtained from the first one by duality: SUMAX_π(f) = 1 − SUMIN_π(1 − f). Pseudo-Boolean counterparts of such aggregation methods are

\[ DUMAX_\pi(f) = \bigvee_{i: f_i > \pi_i} \pi_i; \quad DUMIN_\pi(f) = \bigwedge_{i: f_i < 1 - \pi_i} 1 - \pi_i, \]

which are De Morgan duals. The study of such methods is a topic for further research.
4. Variants of qualitative integrals

This part focuses on the generalisation of the qualitative weighted aggregation schemes presented in the previous part to the case where weights are directly assigned to subsets of criteria rather than to individual ones only. This kind of approach enables various kinds of interactions between criteria to be taken into account. Note that in the demanding aggregation schemes using SLMIN, STMIN and DTMIN, there is a synergy between criteria (they need to be all fulfilled), while in the loose aggregation schemes, using SLMAX, STMAX and DTMAX, the criteria are more or less redundant. We consider more general forms of interaction here.

4.1. Sugeno integral

Importance levels can be assigned to sets of criteria (instead of single ones) by means of a capacity which is a mapping $\gamma : 2^X \to L$ such that $\gamma(\emptyset) = 0$, $\gamma(X) = 1$, and if $A \subseteq B$ then $\gamma(A) \leq \gamma(B)$. The conjugate $\gamma^\ast(A)$ of capacity $\gamma$ is a capacity defined by $\gamma^\ast(A) = 1 - \gamma(\overline{A})$, $\forall A \subseteq C$. This generalised importance assignment enables dependencies between criteria to be accounted for; namely, redundant criteria in a set $A$ are such that $\gamma(A) = \max_{i \in A} \gamma\{i\}$, while a synergy between them is expressed when $\gamma(A) > \max_{i \in A} \gamma\{i\}$.

A special case of capacity is a possibility measure [12,42] which is a maxitive capacity, i.e., a capacity $\Pi$ such that $\Pi(A \cup B) = \Pi(A) \cup \Pi(B)$. Since the set of criteria is finite, the possibility distribution $\pi : \pi(i) = \Pi\{i\}$ here representing criteria weights, is enough to recover the set-function: $\forall A \subseteq C$, $\Pi(A) = \bigvee_{i \in A} \pi(i)$. In this case, criteria are considered redundant with one another, since the weight of group $A$ is the one of the most important criterion in it.

The conjugate of a possibility measure $\Pi$ is a necessity measure $N(A) = 1 - \Pi(\overline{A})$, and then $N$ is a minitive capacity, i.e., $N(A \cap B) = N(A) \cap N(B)$, Moreover, $N(A) = \bigwedge_{i \in A} \pi(i)$ where $\pi(i) = N(C \setminus \{i\})$ (this is the degree of possibility of $i$ when dealing with uncertainty), and $\pi(i) = 1 - \pi(i)$, where $\pi$ defines the conjugate possibility measure $\Pi = N^\ast$. In a group $A$ of criteria, we may have $N\{i\} = 0$ $\forall i \in A$ but $N(A) > 0$ which suggests that necessity measures account for criteria in positive synergy.

The usual generalisation of the prioritised maximum $SLMAX_r$ and the prioritised minimum $SLMIN_r$, is the well-known Sugeno integral widely used to aggregate qualitative local evaluations in multiple attribute evaluation [38]:

$$\int_{\gamma^\ast}^f (f) = \bigvee_{A \subseteq C} \left( \gamma(A) \wedge \bigwedge_{i \in A} f_i \right) \quad (12)$$

The notation $\int_{\gamma^\ast}$, letting the capacity symbol appear as a subscript, is unusual for integrals. It is conveniently concise for this paper where the domain plays no particular role.

It is easy to see (and well-known [9,31]) that if the capacity is a possibility measure, $f_{\Pi^\ast}(f) = SLMAX_r(f)$. Indeed, letting $j \in A$ be such that $\pi_j = \Pi(A)$, it is obvious that $\Pi(A) \wedge \bigwedge_{i \in A} f_i \leq \pi_j \wedge f_j$.

There are alternative expressions of Sugeno integral as follows [17,34,35,38,39]:

$$\int_{\gamma^\ast}^f (f) = \bigvee_{A \subseteq C} \left( \gamma(A) \wedge \bigwedge_{i \in A} f_i \right) = \bigwedge_{A \subseteq C} \left( \gamma(\overline{A}) \vee \bigvee_{i \in A} f_i \right) \quad (13)$$

$$= \bigvee_{i=1}^n f_i \wedge \gamma\{i, \ldots, n\} = \bigwedge_{i=1}^n f_i \vee \gamma\{i+1, \ldots, n\}. \quad (14)$$

$$= \bigvee_{a \in L} a \wedge \gamma\{i : f_i \geq a\} = \bigwedge_{a \in L} a \vee \gamma\{i : f_i > a\}. \quad (15)$$

where we have supposed $f_1 \leq \cdots \leq f_n$ as it is requested at the beginning of Section 2.

Note that Sugeno integral has exponential complexity in terms of the number of criteria, but can be reduced to an expression of linear size.

To make the rest of the paper easier to read it is useful to recall how these properties are justified, as well as some other related properties.

**Lemma 1.** $\bigvee_{A \subseteq C} \gamma(A) \wedge \bigwedge_{i \in A} f_i = \bigvee_{i=1}^n f_i \wedge \gamma\{i, \ldots, n\}$.

**Proof.** If $f_j = \bigwedge_{i \in A} f_i$, then $A \subseteq \{j, \ldots, n\}$, so $\forall A \subseteq C$, $f_j \wedge \gamma\{j, \ldots, n\} \geq \gamma(A) \wedge \bigwedge_{i \in A} f_i$. $\square$

**Lemma 2.** $\bigwedge_{A \subseteq C} \gamma(\overline{A}) \vee \bigwedge_{i \in A} f_i = \bigwedge_{i=1}^n f_i \vee \gamma\{i+1, \ldots, n\}$.

**Proof.** If $f_j = \bigwedge_{i \in A} f_i$, then $A \subseteq \{1, \ldots, j\}$, i.e., $\{j+1, \ldots, n\} \subseteq \overline{A}$. So, $\forall A \subseteq C$, $f_j \vee \gamma\{j+1, \ldots, n\} \leq \gamma(\overline{A}) \vee \bigwedge_{i \in A} f_i$. $\square$

**Lemma 3.** $\int_{\gamma^\ast} f (f) = \bigwedge_{i=1}^n f_i \wedge \gamma\{i, \ldots, n\} = \bigwedge_{i=1}^n f_i \vee \gamma\{i+1, \ldots, n\}$.

**Proof.** The $f_i$ form an increasing sequence, and $g_i = \gamma\{i, \ldots, n\}$ form a decreasing sequence. Since $g_1 = 1$, $\bigwedge_{i=1}^n f_i \wedge g_i$ is the median of $\{f_1, \ldots, f_n\} \cup \{g_2, \ldots, g_n\}$ ([11], Proposition 1). Likewise, since $g_{n+1} = 0$, $\bigwedge_{i=1}^n f_i \vee g_{i+1}$ is the median of the same set of numbers ([11], Proposition 2). $\square$
These results make it easy to realise that [31,35]:

**Corollary 1.** For a necessity measure \( N \) based on possibility distribution \( \pi : f_N(f) = \text{SLMIN}_\pi(f) \).

**Proof.** \( f_N(f) = \bigwedge_{i=1}^n f_i \vee N([i+1, \ldots, n]) = \bigwedge_{i=1}^n f_i \vee (\bigwedge_{j=i}^n 1 - \pi_j) \). If the minimum were reached for \( i > j \), one would have \( f_N(f) = f_i \vee (1 - \pi_j) \), but note that \( f_i \vee (1 - \pi_j) \geq f_j \vee (1 - \pi_j) \). So the minimum is reached for \( i = j \). □

Sugeno integral can be rewritten using the Kleene implication \( \rightarrow_D \) and conjunction \( \ast_D \), which highlights the connection between the two forms of Sugeno integral and the two families of optimistic and pessimistic aggregation operations laid bare in the previous section. Consider the following expressions:

\[
\bigvee_{A \in C} \gamma(A) \ast_D \bigwedge_{i \in A} f_i \text{ and } \bigvee_{A \in C} \gamma^\ast(A) \rightarrow_D \bigwedge_{i \in A} f_i.
\]

As recalled above, these are two forms of Sugeno integral that satisfy the following equalities:

\[
\bigvee_{A \in C} \gamma(A) = \bigvee_{A \in C} \gamma^\ast(A) \rightarrow_D \bigwedge_{i \in A} f_i.
\]

\[
A = \bigvee_{A \in C} \gamma(A) \ast_D \bigwedge_{i \in A} f_i = \bigvee_{A \in C} \gamma^\ast(A) \rightarrow_D \bigwedge_{i \in A} f_i.
\]

Note that \( f^{\ast\wedge}_\gamma(f) \) is a generalised normal disjunctive form usual in logic, while \( f^{\ast\vee}_\gamma(f) \) is a generalised normal conjunctive form of the same aggregation operation.

Finally, there is a duality relation between Sugeno integrals with respect to conjugate capacities:

**Proposition 2.** \( f^{\ast\wedge}_\gamma(f) = 1 - f^{\ast\vee}_\gamma(1 - f) \).

**Proof.** \( 1 - f^{\ast\vee}_\gamma(1 - f) = 1 - \bigwedge_{A \in C} \gamma^\ast(A) \vee (\bigvee_{i \in A} 1 - f_i) = \bigvee_{A \in C} 1 - \gamma^\ast(A) \wedge (\bigvee_{i \in A} f_i) \). □

### 4.2. Common properties of qualitative integrals

We are now in a position to propose generalisations of other weighted aggregations in a similar way as above, changing Kleene implication into Gödel implication and its contrapositive form, as well as the associated conjunctions obtained by the Kleene negation. We get four residuation-based aggregation operations, that mimic the two forms (disjunction of conjunctions and conjunction of implications) of Sugeno integral given in Eq. (13):

**Definition 1.**

**Soft integrals** Conjointive form:

\[
\bigvee_{A \in C} \gamma^\ast(A) \rightarrow_D \bigwedge_{i \in A} f_i = \bigwedge_{A \in C : \bigvee_{i \in A} f_i \geq \gamma^\ast(A)} \bigvee_{i \in A} f_i;
\]

Disjunctive form:

\[
\bigvee_{A \in C} \gamma(A) \ast_D \bigwedge_{i \in A} f_i = \bigwedge_{A \in C : \bigwedge_{i \in A} f_i \geq 1 - \gamma(A)} \bigvee_{i \in A} f_i.
\]

**Drastic integrals** Conjointive form:

\[
\bigvee_{A \in C} \gamma^\ast(A) \rightarrow_D \bigwedge_{i \in A} f_i = \bigwedge_{A \in C : \bigvee_{i \in A} f_i \leq \gamma^\ast(A)} (1 - \gamma^\ast(A));
\]

Disjunctive form:

\[
\bigvee_{A \in C} \gamma(A) \ast_D \bigwedge_{i \in A} f_i = \bigwedge_{A \in C : \bigwedge_{i \in A} f_i \leq 1 - \gamma(A)} \gamma(A).
\]

Note that the drastic integrals can be written more directly in terms of Gödel connectives as:

\[
\bigvee_{A \in C} \gamma^\ast(A) \rightarrow_D \bigwedge_{i \in A} (1 - f_i) = \gamma(A)
\]

and

\[
\bigvee_{A \in C} \gamma(A) \ast_D \bigwedge_{i \in A} f_i = \gamma^\ast(A).
\]

A generalised version of property of duality between the conjunction-based and the implication-based aggregation schemes holds for all these integrals:

**Proposition 2.** \( f^{\ast\wedge}_\gamma(f) = 1 - f^{\ast\vee}_\gamma(1 - f) \) where \( (\rightarrow, \ast) \in \{ (\rightarrow_D, \ast_D), (\rightarrow_G, \ast_G) \} \).
Proof. $1 - f_N^\gamma (1 - f) = 1 - (\wedge_{A \in C} \gamma(A) \rightarrow \vee_{i \in A} (1 - f_i))$
$= \wedge_{A \in C} 1 - (\gamma(A) \rightarrow 1 - \wedge_{i \in A} f_i) = f_N^\gamma (f)$. □

Like Sugeno integral, the residuation-based integrals have exponential complexity in terms of the number of criteria. We now show that these residuation-based expressions can be simplified in terms of equivalent forms in a way similar to Sugeno integral. Namely, they can be reduced to an expression of linear size similar to (14):

Proposition 3. $f_N^\gamma (f) = \wedge_{i=1}^n (\gamma_i(\overline{A_{i+1}}) \rightarrow f_i)$ and $f_S^\gamma (f) = \wedge_{i=1}^n \gamma_i(A_i) \bullet f_i$
where $\rightarrow \in \{ \rightarrow_G, \rightarrow_C, \rightarrow_{GC}, \rightarrow_{GCC} \}$ and $A_i = [i, \ldots, n]$.

Proof. $f_N^\gamma (f) = \wedge_{i=1}^n (\gamma_i(\overline{A_{i+1}}) \rightarrow f_i) \wedge \wedge_{A \in (\overline{A_2}, \ldots, \overline{A_n})} (\gamma(A) \rightarrow \vee_{i \in A} f_i)$.

We consider $A \in (\overline{A_2}, \ldots, \overline{A_n})$ and let $f_k = \vee_{i \in A} f_i$.
Now, $A \subseteq \overline{A_{k+1}}$. Then clearly $\gamma_i(A) \leq \gamma_i(\overline{A_{k+1}})$.
So $\gamma_i(A) \rightarrow \vee_{i \in A} f_i \geq \gamma_i(\overline{A_{k+1}}) \rightarrow f_k \geq \wedge_{i=1}^n \gamma_i(\overline{A_{i+1}}) \rightarrow f_k$.
For the integral using the conjunction, we denote $\vee_{i \in A} f_i = f_k$. Then $\wedge_{i \in A} f_i = f_k$ is maximal for $A = A_k$, and so is $\gamma(A)$ among all $A$ such that $\wedge_{i \in A} f_i = f_k$. □

Sugeno integral can also be written as: $f_N^\gamma (f) = \vee_{v \in A} a \wedge \gamma(i : f_i \geq a)$ (Eq. (15)). The soft integrals and the drastic integrals have similar expressions:

Proposition 4. $f_N^\gamma (f) = \vee_{v \geq a} \gamma((f \geq a)) \bullet a$,
$f_S^\gamma (f) = \wedge_{v \leq a} \gamma((f > a)) \rightarrow a = \wedge_{v \leq a} \gamma((f \leq a)) \rightarrow a$.
where $\rightarrow \in \{ \rightarrow_G, \rightarrow_C, \rightarrow_{GC}, \rightarrow_{GCC} \}$.

Proof. We have $f_S^\gamma (f) = \vee_{v=1}^n \gamma(A_i) \bullet f_i$. Let us consider $a \in L$.

- If $\exists i$ such that $a = f_i$ then $\gamma((f \geq a)) \bullet a = \gamma(A_i) \bullet f_i$ (we take the least index $i$ such that $f_i = a$).
- If $a > f_0$ then $\gamma((f \geq a)) = \gamma(0) = 0$ hence $\gamma((f \geq a)) \bullet a = 0$.
- Otherwise let us denote $i$ the index such that $f_{i-1} < a < f_i$. In such a context we have $\gamma((f \geq a)) \bullet a = \gamma(A_i) \bullet a$ which entails $\gamma((f \geq a)) \bullet a \leq \gamma(A_i) f_i$.

So we have $\vee_{v \geq a} \gamma((f \geq a)) \bullet a = \vee_{v \geq a} \gamma(A_i) \bullet f_i$.
Using Proposition 2 we have $f_N^\gamma (f) = 1 - f_S^\gamma (1 - f) = 1 - \vee_{v \leq a} \gamma((1 - f \geq a)) \bullet a$.

This is equal to $\wedge_{v \leq a} \gamma((1 - f \geq a)) \rightarrow (1 - a)$ since $\alpha \rightarrow (1 - \beta) = 1 - (\alpha \wedge \beta)$, by definition. It also reads, replacing $1 - a$ by $a$: $\wedge_{v \leq a} \gamma((f \leq a)) \rightarrow a$. □

As recalled in the previous subsection, the weighted aggregations $SLMIN_\pi$ and $SLMAX_\pi$ are particular cases of the Sugeno integral, obtained by means of a necessity and a possibility measure, respectively. Similarly, soft integrals extend aggregations $STMIN_\pi(f), STMAX_\pi(f)$, and drastic ones extend $DTMIN_\pi(f), DTMAX_\pi(f)$.

Proposition 5.

- If $\gamma$ is a necessity measure $N$, then $f_N\gamma f^{-} = STMIN_\pi$ and $f_N\gamma f^{+} = DTMIN_\pi$.

- If $\gamma$ is a possibility measure $\Pi$ then $f_N\gamma f^{-} = STMAX_\pi$, and $f_N\gamma f^{+} = DTMAX_\pi$.

Proof. If $\gamma$ is a necessity measure then $\gamma$ is a possibility measure $\Pi$ based on possibility degrees $\pi_i, i = 1, \ldots, n$.

- For each index $i$, there exists a subset $B_i$ such that $\pi_i = \Pi(B_i)$. It is then obvious that $f_N\gamma f^{-} (f) \leq STMIN_\pi (f)$ and $f_N\gamma f^{+} (f) \leq DTMIN_\pi (f)$ as the integrals consider the minimum overlap over many more situations.

- Now let $A$ be a set such that $f_N\gamma f^{-} (f) = \vee_{i \in A} \pi_i \rightarrow_G \vee_{i \in A} f_i$. Let $k, i$ such that $f_N\gamma f^{-} (f) = \pi_k \rightarrow_G f_i$. If $\pi_k \rightarrow_G f_i = 1$, then $f_N\gamma f^{-} (f) \geq STMIN_\pi (f)$ is obvious. Otherwise $\pi_k \rightarrow_G f_i = f_i < 1$. But by construction $f_i \geq f_k$. Hence $f_N\gamma f^{-} (f) = f_i \geq \pi_k \rightarrow_G f_k \geq STMIN_\pi (f)$.

Similarly for the drastic integral let us denote $f_N\gamma f^{+} (f) = \pi_k \rightarrow_G f_i$. By construction $f_i \leq \cdots \leq f_k \leq \cdots \leq f_i$ and $\pi_i \leq \pi_k$.

- $f_N\gamma f^{+} (f) = 1$ then $f_N\gamma f^{+} (f) \geq DTMIN_\pi (f)$.

- $f_N\gamma f^{+} (f) = 1 - \pi_\pi \rightarrow f_i = f_i \geq f_k$.

so $f_N\gamma f^{+} (f) = \pi_k \rightarrow_G f_k \geq DTMIN_\pi (f)$.

If $\gamma$ is a possibility measure, using the relation between the implication and the conjunction we have $f_PN (f) = 1 - f_N^{-} (1 - f)$
where $N = \Pi^\dagger$ is a necessity measure. Hence we conclude using the relation between the simple weighted aggregations. □

4.3 Properties specific to residuation-based integrals

There is a major difference between Sugeno integrals and its residuation-based variants: the counterpart of equality (16) satisfied by the Sugeno integral is not true for the soft and the drastic desintegrals. More precisely $f_N\gamma f^{-} \neq f_PN f^{-}$ and $f_N\gamma f^{+} \neq f_PN f^{+}$. In particular we cannot change $\rightarrow \rightarrow \rightarrow \rightarrow$ into $\bullet$, or conversely, in Proposition 5. Contrary to the case of Sugeno integrals expressions of $f_N\gamma f^{-} (f)$ and $f_PN (f)$ are not obvious to simplify, while $f_PN f^{-} (f)$ and $f_PN f^{+} (f)$ reduce to simple weighted aggregations.
In the case of Sugeno integral, written in conjunctive form, the condition for the same thresholds to test the local ratings. The second case in the example uses a Boolean capacity so that it shows an extreme.

**Table 1**  Differences between disjunction-\& conjunction-implication forms of residuation-based aggregations.

</tr>
</tbody>
</table>

In fact, we can prove inequalities only, as a by-product of Proposition 3:

**Corollary 2.** \( f_{\gamma, \gamma} \geq f_{\gamma, \gamma} \) and \( f_{\gamma, \gamma} \geq f_{\gamma, \gamma} \).

**Proof.** First write the expressions of residuation-based integrals in the form \( f_{\gamma, \gamma} = \bigvee_{A \subseteq \Omega} f_i \) and \( f_{\gamma, \gamma} = \bigwedge_{A \subseteq \Omega} f_i \) where \( \gamma^e(A) = 1 - \gamma(A) \). By definition, \( 1 - \gamma(A_{i+1}) \geq 1 - \gamma(A_i) \). Hence \( \bigvee_{A \subseteq \Omega} f_i \geq \bigwedge_{A \subseteq \Omega} f_i \).

Now, \( f_{\gamma, \gamma} = \bigvee_{A \subseteq \Omega} f_i \) and \( f_{\gamma, \gamma} = \bigwedge_{A \subseteq \Omega} f_i \) where \( f_{\gamma, \gamma} = \bigvee_{A \subseteq \Omega} f_i \) and \( f_{\gamma, \gamma} = \bigwedge_{A \subseteq \Omega} f_i \). Let \( i \) be an index such that \( f_{\gamma, \gamma} = \gamma(A_i) \). Hence \( \gamma(A_i) = 1 - \gamma(A_{i+1}) \leq 0 \), so we have \( \gamma(A_i) \leq f_{\gamma, \gamma} \).

So, the disjunction-\& forms are more liberal than their conjunctive implication-based counterparts. The difference between \( f_{\gamma, \gamma} \) and \( f_{\gamma, \gamma} \), as well as between \( f_{\gamma, \gamma} \) and \( f_{\gamma, \gamma} \) can be extreme, as indicated in Table 1 by the cases when these expressions take values 0 or 1, which correspond to different conditions.

The cases where \( f_{\gamma, \gamma} = 1 \) and \( f_{\gamma, \gamma} = 0 \) are the same as their counterparts for the soft thresholding integrals. The threshold-based nature of \( f_{\gamma, \gamma} \) (resp. \( f_{\gamma, \gamma} \)) can be seen by the weak condition under which it vanishes (resp. it is maximal). This table sheds some light on the intuitive meanings of these aggregation operations.

- For \( f_{\gamma, \gamma} \) to be large, you need to have in each subset \( A \) of criteria one that is satisfied at degree \( \gamma(A) \). The same requirement holds for \( f_{\gamma, \gamma} \) to be large. This requirement may look more natural than the one (first line) that ensures that Sugeno integral is high. Besides \( f_{\gamma, \gamma} \) vanishes if the local ratings are very bad on all criteria in a group of dual positive importance \( \gamma(A) \). This condition brings the global evaluation to zero more often than the one that brings Sugeno integral to zero. Note that for this aggregation, the thresholds are determined by \( \gamma(A) \), because the form of the expression is a conjunction of implications.

- For \( f_{\gamma, \gamma} \) to be large, you only need to find one set \( A \) of criteria where all local ratings pass the threshold \( 1 - \gamma(A) \) (it is low for important groups of criteria); this is much less demanding than for Sugeno integral. In contrast \( f_{\gamma, \gamma} \) is low as soon as for all subsets of criteria, the local rating pertaining to them fails to pass this threshold. The same condition keeps \( f_{\gamma, \gamma} \) at a low value.

- \( f_{\gamma, \gamma} \) is low whenever there is a fully important group of criteria \( A \) with \( \gamma(A) = 1 \) for which no local rating is maximal, which is drastic indeed. On the other hand, \( f_{\gamma, \gamma} \) is large as soon as all local ratings are positive for a group of criteria with maximal importance \( \gamma(A) = 1 \).

Extreme discrepancies between the disjunctive and conjunctive forms can be observed on very simple examples:

**Example 1.**
- Let us consider \( C = \{1, 2\} \), a capacity \( \gamma \) such that \( 1 > \gamma([2]) = 0 \), and an object \( f \) such that \( f_1 = 0 \) and \( f_2 = 1 \). Hence \( f_{\gamma, \gamma} \leq \gamma([1]) \rightarrow f_1 = 0 \) and \( f_{\gamma, \gamma} \geq 1 - \gamma([2]) \rightarrow f_2 = 1 \). So the conjunctive expression judges \( f \) to be very bad because it has a very bad local rating for criterion 1 which matters since its weight is assessed using \( \gamma(A) \) (even if \( \gamma([1]) = 0 \)). The disjunctive expression considers \( f \) very good as its local rating on criterion 2 is maximal and criterion 2 is of positive importance (according to \( \gamma \)).
- Let us consider \( C = \{1, 2\} \), a capacity \( \gamma \) such that \( \gamma([2]) = 0 \), \( \gamma([1]) = 1 \) and an object \( f \) such that \( 0 < f_1 < 1 \). Then \( f_{\gamma, \gamma} \leq \gamma([1]) \rightarrow f_1 = 0 \) and \( f_{\gamma, \gamma} \geq \gamma([1]) \). Here the conjunctive expression finds \( f \) very bad because the local rating on one maximally important criterion is not maximal. While the disjunctive expression finds \( f \) excellent because the local rating on a maximally important criterion is not zero.

The first case in the example spots the reason for the discrepancy: conjunctive and disjunctive expressions do not use the same thresholds to test the local ratings. The second case in the example uses a Boolean capacity so that it shows an extreme discordance between the disjunctive and conjunctive drastic criteria even in this case.

**Remark 3.** In the case of Sugeno integral, written in conjunctive form, the condition for \( f_{\gamma} = 1 \) reads: \( \forall B, f_{\gamma}(B) < 1 \) then \( \exists i \in B, f_i = 1 \). This is not obviously equivalent to the condition obtained from the disjunctive form in Table 1: \( \exists A, \gamma(A) = 1 \) and \( \forall i \in A, f_i = 1 \). Proving the equivalence requires some elaboration:
• From disjunctive to conjunctive: suppose $\exists A, \gamma (A) = 1$ and $\forall i \in A, f_i = 1$. Consider a set $B$. If $B = A$, the pre-condition $\gamma(B) < 1$ does not apply. As $\gamma$ is a capacity, we can dispense with the case when $B$ contains $A$. Then we can restrict to the case when $\exists i \in A \mid B \neq \emptyset$; by construction $f_i = 1$.

• From conjunctive to disjunctive: suppose $\forall B$, if $\gamma(B) < 1$ then $\exists i \in B, f_i = 1$. Let $A = \{i : f_i = 1\}$. This set is not empty since $\gamma(\emptyset) = 0$. Now it is clear that $\gamma(A) = 1$ as $f_i < 1$ whenever $i \notin A$, by construction.

For Boolean capacities $\beta$ (i.e., $\beta(A) \in \{0,1\}$), the conditions in Table 1 reduce to:

- $f^\circ_B(f) = f^\circ_B(c)(f) = 1$ if and only if for all $A$ such that $\beta(A) = 1$, $\exists i \in A, f_i = 1$;
- $f^\circ_B(f) = f^\circ_B(c)$ otherwise. If $f_i > 0$, $\forall i \in A$, for some $A$ for which $\beta(A) = 1$.
- $f^{-\circ}_B(f) = f^{-\circ}_B(c)(f) = 0$ if and only if for all $A$ such that $\beta(A) = 1$, $\exists i \in A, f_i = 0$;
- $f^{-\circ}_B(f) = f^{-\circ}_B(c)$ otherwise. If $f_i > 0$, $\forall i \in A$, for some $A$ with $\beta(A) = 1$.

The first condition is violated in the second part of Example 1 because $f_1 < 1$ while the second condition is satisfied because $f_1 > 0$. We shall always observe this discrepancy in this case.

It is worth noticing that equality (16) between disjunctive and conjunctive forms only holds for the drastic integrals when $f$ is the characteristic function $\mu_B$ of a subset $B$. Then

$$\int f^\circ_B (\mu_B) = \int f^{-\circ}_B (\mu_B) = \gamma(B).$$

However, we have the following result for soft integrals:

**Proposition 6.** $\int f^\circ_B (\mu_B) = \begin{cases} 1 & \text{if } \gamma(B) = 1 \\ 0 & \text{otherwise} \end{cases}$ and $\int f^{-\circ}_B (\mu_B) = \begin{cases} 1 & \text{if } \gamma(B) > 0 \\ 0 & \text{otherwise} \end{cases}$.

**Proof.** If $A \cap B \neq \emptyset$, $\exists i \in A, f_i = 1 \geq \gamma^c(A)$, and $\gamma^c(A) \rightarrow \gamma^c(\forall iA f_i) = 1$; if $A \cap B = \emptyset$, then $f_i = 0$, $\forall i \in A$ so you need $\gamma^c(A) = 0$ to get $\gamma^c(\forall iA f_i) = 1$. Now the condition reads $\gamma^c(A) = 0$, $\forall A \cap B = \emptyset$. It can also read $\gamma(A) = 1$, $\forall A : B \subseteq A$; but since $\gamma$ is monotonic, this is equivalent to $\gamma(\emptyset) = 1$.

For the second expression, if $A \subseteq B$, then $\wedge_i A f_i = 0$. Otherwise, $\wedge_i A f_i = 1 = f^\circ_B(\mu_B)$, provided that $\gamma(A) > 0$. So $f^\circ_B(\mu_B) = 1$ if and only if $\exists B \subseteq A, \gamma(A) > 0$. This is equivalent to $\gamma(B) > 0$ from monotonicity. \(\square\)

In fact the above result also shows the following invariance property: given a capacity $\gamma$, define the Boolean capacity $\gamma_\beta$ such that $\gamma_\beta(A) = 1$ if $\gamma(A) = 1$ and 0 otherwise. Likewise define $\gamma_\beta$ such that $\forall A \subseteq C, \gamma_\beta(A) = 1$ if $\gamma(A) > 0$ and 0 otherwise. Then it is easy to see that, $\forall B \subseteq C$,

$$\int f^\circ_B (\mu_B) = \int f^\circ_B (\mu_B) = \gamma(B); \quad \int f^{-\circ}_B (\mu_B) = \int f^{-\circ}_B (\mu_B) = \gamma(B).$$

Since $\gamma_\beta \geq \gamma$, the above proposition actually confirms that $f^\circ_B(\mu_B) \leq f\gamma_\beta(\mu_B)$, that is, the former is more demanding than the latter. We have seen by Corollary 2 that this inequality always holds for general functions $f$. It also confirms the lack of equality between $f^\circ_B(f)$ and $f^{-\circ}_B(f)$. However note that if $f$ reduces to a crisp set $B$, $f^\circ_B(\mu_B) = \gamma(B)$, $f^{-\circ}_B(\mu_B) = \gamma^c(B)$, and $\gamma$ is conjugate to $\gamma^c$ (i.e. $\gamma^c \gamma = 1$): $\gamma(B) = 1 - \gamma^c(B)$. The connection between and $f^\circ_B(f)$ and $f^{-\circ}_B(f)$ for general functions remains to be studied.

As, in general, $f^\circ_B(\mu_B)$ and $f^{-\circ}_B(\mu_B)$ are not equal to $\gamma(B)$, none of these “integrals” extends the capacity from Boolean to non-Boolean events. Hence, neither $f^\circ_B$ nor $f^{-\circ}_B$ is a universal integral in the sense defined in [33]. $f^\circ_B$ and $f^{-\circ}_B$ are not universal integrals either since in general

$$\int \gamma(c \wedge \mu_B) \neq \gamma(c \wedge \gamma(B)) \quad \text{and} \quad \int \gamma(c \wedge \mu_B) \neq \gamma(c \wedge \gamma(B)).$$

**Example 2.** We consider $C = \{1, 2\}$, $L = [0, 1]$, the capacity $\gamma$ such that $\gamma(\{1\}) = \gamma(\{2\}) = 0.5$ and $c = 0.2$. Hence

- $f^\circ_B(0.2, 0.5) = 0$ and $0.2 \wedge f^\circ_B(0.2) = 0.2$.
- $f^{-\circ}_B(0.2, 0.5) = 0$ and $0.2 \wedge f^{-\circ}_B(0.2) = 0.2$.

4.4. Residuation-based integrals as upper and lower possibilistic aggregations

It has been noticed [15] that the set $\{\pi : \Pi(A) \geq \gamma(A), \forall A \subseteq C\}$ of possibility distributions whose associated possibility measures $\pi$ dominate a given capacity $\gamma$ is never empty. We call this set the *possibilistic core* of $\gamma$ [20], which, in this paper we denote by $S(\gamma)$, by similarity with game theory [37], where the core of a capacity is the (possibly empty) set of probability measures that dominate it.

There is always at least one possibility measure that dominates any capacity: the vacuous possibility measure, based on the distribution $\pi^\emptyset$, expressing ignorance, since then $\forall A \neq \emptyset \subset C, \Pi^\emptyset(A) = 1 \geq \gamma(A), \forall \gamma$ capacity $\gamma$, and $\Pi^\emptyset(\emptyset) = \gamma(\emptyset) = 0$. 
Some possibility distributions in the core can be generated by permutations of elements. Let $\sigma$ be a permutation of the $n = |C|$ elements in $C$. The $i$th element of the permutation is denoted by $\sigma(i)$. Moreover let $C_{\sigma} = \{\sigma(i), \ldots, \sigma(n)\}$. Define the possibility distribution $\pi^C_{\sigma}$ as follows:

$$\forall i = 1, \ldots, n, \pi^C_{\sigma}(\sigma(i)) = \gamma(C_1).$$

There are at most $n!$ (number of permutations) such possibility distributions which are named the marginals of $\gamma$. It can be checked that the possibility distribution $\pi^C_{\sigma}$ lies in $S(\gamma)$ and that the $n!$ such possibility distributions enable $\gamma$ to be reconstructed (as already pointed out by Banon [1]). More precisely,

$$\forall A \subseteq C, \gamma(A) = \bigwedge_{\sigma} \Pi^C_{\sigma}(A).$$

There are at most $n!$ (number of permutations) such possibility distributions which are named the marginals of $\gamma$. It can be checked that the possibility distribution $\pi^C_{\sigma}$ lies in $S(\gamma)$ and that the $n!$ such possibility distributions enable $\gamma$ to be reconstructed (as already pointed out by Banon [1]). More precisely,

$$\forall A \subseteq C, \gamma(A) = \bigwedge_{\sigma} \Pi^C_{\sigma}(A).$$

A possibility measure $\Pi_1$ is said to be more specific than another possibility measure $\Pi_2$ if $\forall A \subseteq C, \Pi_1(A) \leq \Pi_2(A)$ (equivalently $\forall i \in C, \Pi_1(i) \leq \Pi_2(i)$). In fact, $\pi^C$ is the unique maximal element of $S(\gamma)$ for this ordering.

In the qualitative case, $S(\gamma)$ is closed under the qualitative counterpart of a convex combination or mixture: namely, if $\pi_1, \pi_2 \in S(\gamma)$ then $\forall a, b \in L$, such that $a \lor b = 1$, it holds that $(a \land \pi_1) \lor (b \land \pi_2) \in S(\gamma)$, and $(a \land \pi_1) \lor (b \land \pi_2)$ is a possibility measure too [13]. In fact, $S(\gamma)$ is an upper semi-lattice. Let $\mathcal{S}_c = \{S \subseteq S(\gamma) \mid \mathcal{S}_c\}$ be the set of minimal elements in $S(\gamma)$.

Besides, it follows from the definition of the possibilistic core that $\gamma(A) = \bigwedge_{\Pi \in \mathcal{S}(\gamma)} \Pi(A)$, and thus any possibility interval can be viewed either as a lower possibility measure or as an upper necessity measure, defined on the minimal possibility distributions in the core.

**Proposition 7** ([5,21]).

$$\gamma(A) = \bigwedge_{\pi \in \mathcal{S}_c(\gamma)} \Pi(A) = \bigvee_{\pi \in \mathcal{S}_c(\gamma^c)} N(A)$$

The second equality can be obtained by applying the first one to $\gamma^c$.

Note that Sugeno integral can be written as a prioritised maximum. Let $\pi^f$ be the marginal of $\gamma$ obtained from a permutation determined by the function $f$. Namely, as $f_1 \leq \cdots \leq f_n$, define $\pi^f_i = \gamma(A_i)$, where $A_i = \{i, \ldots, n\}$. Then it is clear that $\Pi^f(A_i) = \gamma(A_i)$, and Sugeno integral, in the form (14):

$$\int_{\gamma^f}(f) = \int_{\Pi^f}(f) = \bigvee_{i=1}^n f_i \land \pi^f_i = \text{SLMAX}_{\pi^f}(f)$$

Likewise, letting $\pi^f_i = 1 - \gamma(\{i+1, \ldots, n\}) = 1 - \pi^f_i$ denote the degree of possibility of $i$ determined by the opposite permutation, Sugeno integral after the right-hand side of (14) can be written as a prioritised minimum:

$$\int_{\gamma^f}(f) = \int_{\Pi^f}(f) = \bigwedge_{i=1}^n f_i \lor (1 - \pi^f_i) = \text{SLMIN}_{\pi^f}(f)$$

As a consequence of this result, it was proved in [5,21] that Sugeno integral is a lower prioritised maximum, as well as an upper prioritised minimum:

**Proposition 8.**

$$\int_{\gamma^f}(f) = \bigwedge_{\pi \in \mathcal{S}_c(\gamma)} \Pi^f(f)$$

where $\int_{\gamma^f}(f) = \bigwedge_{\pi \in \mathcal{S}_c(\gamma^c)} \Pi^f(f)$.

**Proof.** Viewing $\gamma$ as a lower possibility, it comes (with $f_0 = \bigwedge_{i \in A} f_i$): $\int_{\gamma^f}(f) = \bigwedge_{\pi \in \mathcal{S}_c(\gamma^c)} \Pi^f(f) = \bigwedge_{\pi \in \mathcal{S}_c(\gamma^c)} \bigwedge_{\pi \in \mathcal{S}_c(\gamma^c)} \Pi^f(f)$, hence $\int_{\gamma^f}(f) = \bigwedge_{\pi \in \mathcal{S}_c(\gamma)} \Pi^f(f)$.

Conversely, let $\pi^f$ be the marginal of $\gamma$ obtained from a permutation determined by the function $f$, which satisfies $\int_{\gamma^f}(f) = \int_{\Pi^f}(f)$ (Eq. (18)). As $\pi^f \in \mathcal{S}(\gamma)$, $\int_{\Pi^f}(f) = \bigwedge_{\pi \in \mathcal{S}_c(\gamma)} \Pi^f(f)$.

Using conjugacy properties, especially Proposition 1, one can prove the second equality. □

Note that in the numerical case, the same feature occurs, namely, lower expectations with respect to a convex possibility set are sometimes Choquet integrals with respect to the capacity equal to the lower probability constructed from this possibility set (for instance convex capacities, and belief functions [4]). However, this is not true for any capacity and any convex possibility set.

We obtain the same results for the residuation-based qualitative integrals.

**Proposition 9.**

$$\int_{\gamma^f}(f) = \bigwedge_{\pi \in \mathcal{S}_c(\gamma^c)} \Pi^f(f)$$

where (→, •) ∈ {↓, ⊙} → {↓, ⊙} C.□

**Proof.** Consider $\pi \in \mathcal{S}_c(\gamma^c)$; then $\Pi(A) = \bigwedge_{i \in A} f_i \leq \gamma^c(A) = \bigwedge_{i \in A} f_i$ and $\int_{\gamma^f}(f) \leq \int_{\Pi^f}(f)$. So we have $\int_{\gamma^f}(f) \geq \bigwedge_{\pi \in \mathcal{S}_c(\gamma^c)} \Pi^f(f)$. Conversely we consider the possibility distribution defined by $\pi(i) = \gamma^c(A_{i+1}) = \gamma^c(\{i+1, \ldots, n\})$. For all $A$ we have $\Pi(A) = \gamma^c(\{i, \ldots, i_A\})$ where $i_A = \bigwedge_{i \in A} i$; so $\Pi(A) = \gamma^c(A)$ i.e., $\pi \in \mathcal{S}_c(\gamma^c)$. Moreover $\Pi(A_{i+1}) = \Pi(\{i+1, \ldots, i\}) = \bigwedge_{\pi \in \mathcal{S}_c(\gamma^c)} \Pi^f(f)$.
\(\gamma'(1, \ldots, n) = \gamma'(\overline{A}_{i\mid i+1})\). So we have \(f_{\gamma'}^- (f) = f_N^- (f)\) where \(N\) is the fuzzy measure associated with the distribution defined above. Hence \(f_{\gamma'}^- (f) \leq \bigwedge_{\pi \in S_i(y)} f_{\gamma}^- (f)\).

If \(\pi \in S_i(y)\), then \(\Pi(A) \to \bigvee_{i\in A} (1 - f_i) \leq \gamma'(A) \to \bigvee_{i\in A} (1 - f_i)\), which entails \(f_{\gamma'}^- (f) \leq f_{\gamma}^- (f)\). So we have \(f_{\gamma'}^- (f) \leq \bigwedge_{\pi \in S_i(y)} f_{\gamma}^- (f)\). Conversely we consider \(\pi\)' the marginal of \(\gamma\). Hence \(f_{\gamma'}^- (f) = f_{\gamma}^- (f) \geq \bigwedge_{\pi \in S_i(y)} f_{\gamma}^- (f)\).

\[\square\]

5. Qualitative aggregation schemes on negative scales

In this part, the evaluation scale for each criterion is decreasing, i.e., 0 is a better score than 1, but the scale of the global evaluation is increasing. In such a context, criteria \(i\) are impediments that justify downgrading an object and the value \(f_i\) is interpreted as a penalty level, degree of defect, intensity of rejection, according to dimension \(i\). So \(f_i\) is all the greater as the penalty is higher with respect to the criterion \(i\), but the global score is all the lower as the local evaluations are higher. The counterpart of the two elementary aggregations on positive scales can be handled by first reversing the negative scales and then aggregating the results as previously, or on the contrary aggregating the negative scores and reversing the global result. We obtain the following elementary qualitative schemes, where the two methods coincide:

- The demanding evaluation is \(\bigwedge_{n=1} (1 - f_i) = 1 - \bigwedge_{n=1} f_i\). In order to obtain a good evaluation, an object needs to have a weak local rejection level on all criteria (i.e., no defect, no penalty on any criterion).
- The loose global evaluation is \(\bigvee_{n=1} (1 - f_i) = 1 - \bigvee_{n=1} f_i\). It is enough to have a very small penalty only on a criterion to obtain a good global evaluation.

5.1. Elementary desintegrals

These two aggregation schemes can be generalised defining permissiveness or tolerance levels \(t_i\), on the criterion \(i\), \(i = 1, \ldots, n\). On negative scales, \(t_i\) is all the greater as the criterion \(i\) is less important. A fully tolerant criterion has \(t_i = 1\) (tolerating high rejection levels) and a fully intolerant criterion has \(t_i = 0\).

Similarly to the importance weights, these permissiveness levels can alter each local evaluation \(f_i\) in different manners. More precisely, \(t_i\) can act as a saturation threshold that blocks the global score under or above a certain value dependent on the tolerance level of criterion \(i\). Alternatively, \(t_i\) can be considered as a threshold under which the decision-maker is perfectly satisfied, the local rating being altered or not if above the threshold. Let us present all these cases in details.

Saturation levels. The result of applying tolerance \(t_i\) to the negative rating \(f_i\) results in a positive rating that cannot be below \(t_i\). Moreover the local rating scale is reversed, which leads to a local positive rating \((1 - f_i) \lor t_i \in [t_i, 1]\) or \((1 - t_i) \land (1 - f_i) \in [0, 1 - t_i]\). An intolerant criterion can affect the global evaluation.

- The corresponding demanding aggregation scheme is

\[SLMIN_i^{neg}(f) = \bigwedge_{i=1} (1 - f_i) \lor t_i = \bigwedge_{i=1} f_i \rightarrow_D t_i = \bigwedge_{i=1} (1 - t_i) \rightarrow_D (1 - f_i).\]

An intolerant criterion can alone down grade the global evaluation and a permissive criterion cannot bring the global evaluation under the level \(t_i\). Note that \(SLMIN_i^{neg}\) is decreasing, and \(SLMIN_i^{neg} (f \lor g) = \min (SLMIN_i^{neg}(f), SLMIN_i^{neg}(g))\).

- The loose aggregation is of the form

\[SLMAX_i^{neg}(f) = \bigvee_{i=1} (1 - t_i) \land (1 - f_i) = \bigvee_{i=1} (1 - t_i) \star_D (1 - f_i).\]

An intolerant criterion can alone enforce a good global evaluation and a tolerant one cannot alone bring to a global evaluation above \((1 - t_i)\). Note that \(SLMAX_i^{neg}\) is decreasing, and that \(SLMAX_i^{neg} (f \land g) = \max (SLMAX_i^{neg}(f), SLMAX_i^{neg}(g))\).

Note that \(SLMIN_i^{neg}(f) = SLMIN_{1 \rightarrow i} (1 - f)\) and likewise, \(SLMAX_i^{neg}(f) = SLMAX_{1 \rightarrow i} (1 - f)\), so we have:

\[SLMAX_i^{neg}(f) = 1 - SLMIN_i^{neg} (1 - f)\]

(20)

Softening thresholds. Here \(t_i\) is viewed as a tolerance threshold such that it is enough not to reach \((f_i \leq t_i)\) (i.e. the defect rating should remain smaller than this threshold) for the impediment associated with the criterion to be totally avoided. So if \(f_i\) is lower than \(t_i\), then \(f_i\) becomes 0 otherwise we keep the local evaluation \(f_i\). Next, the local evaluation is reversed before the aggregation is performed so the local rating \(f_i\) is replaced by \((1 - t_i) \rightarrow_C (1 - f_i)\).

- The corresponding demanding aggregation has the form

\[STMIN_i^{neg}(f) = \bigwedge_{i=1} (1 - t_i) \rightarrow_C (1 - f_i).\]

A completely intolerant criterion is fully satisfied only if \(f_i = 0\). A more permissive criterion is satisfied if \(f_i \leq t_i\) even if \(f_i\) is high. Note that \(STMIN_i^{neg}\) is decreasing, and \(STMIN_i^{neg} (f \lor g) = \min (STMIN_i^{neg}(f), STMIN_i^{neg}(g))\).
• The loose counterpart is

\[ \text{STMAX}_{\gamma}^{\text{neg}}(f) = \bigvee_{i=1}^{n} (1 - t_i) \mathbin{\cdot} \gamma (1 - f_i). \]

A tolerant criterion is taken into account only if \( f_i \) is very low and an intolerant criterion is involved in the global evaluation even if \( f_i \) is high since the condition is \( f_i \neq 1 \). \( \text{STMAX}_{\gamma}^{\text{neg}} \) is decreasing, and we have \( \text{STMAX}_{\gamma}^{\text{neg}}(f \land g) = \text{max} (\text{STMAX}_{\gamma}^{\text{neg}}(f), \text{STMAX}_{\gamma}^{\text{neg}}(g)) \).

Note that \( \text{STMIN}_{\gamma}^{\text{neg}}(f) = \text{STMIN}_{1-\gamma}(1 - f) \) and \( \text{STMAX}_{\gamma}^{\text{neg}}(f) = \text{STMAX}_{1-\gamma}(1 - f) \) so we have

\[ \text{STMAX}_{\gamma}^{\text{neg}}(f) = 1 - \text{STMIN}_{\gamma}^{\text{neg}}(1 - f). \]

**Drastic thresholds.** Here if \( f_i > t_i \) then the local rating is considered bad and the result is set to \( t_i \) on the opposite scale. If \( f_i \leq t_i \) then the local rating is fine and the result is on the opposite scale is 1. It corresponds again to using Gödel implication and now computing \( f_i \rightarrow_C t_i = (1 - t_i) \rightarrow_C (1 - f_i) \).

• The demanding aggregation is

\[ \text{DTMIN}_{\gamma}^{\text{neg}}(f) = \bigwedge_{i=1}^{n} (1 - t_i) \rightarrow_C (1 - f_i). \]

A completely intolerant negative criterion, if fulfilled, can alone downgrade the global evaluation to 0. A more permissive criterion can just downgrade the result to \( t_i \). Note that \( \text{DTMIN}_{\gamma}^{\text{neg}} \) is decreasing, and \( \text{DTMIN}_{\gamma}^{\text{neg}}(f \lor g) = \text{min} (\text{DTMIN}_{\gamma}^{\text{neg}}(f), \text{DTMIN}_{\gamma}^{\text{neg}}(g)) \).

• The loose counterpart is

\[ \text{DTMAX}_{\gamma}^{\text{neg}} = \bigvee_{i=1}^{n} (1 - t_i) \mathbin{\cdot} \gamma (1 - f_i). \]

A completely intolerant criterion can bring the global evaluation to 1. A more permissive criterion cannot bring the global evaluation above 1 – \( t_i \), \( \text{DTMAX}_{\gamma}^{\text{neg}} \) is decreasing, and we have \( \text{DTMAX}_{\gamma}^{\text{neg}}(f \land g) = \text{max} (\text{DTMAX}_{\gamma}^{\text{neg}}(f), \text{DTMAX}_{\gamma}^{\text{neg}}(g)) \).

Note that \( \text{DTMIN}_{\gamma}^{\text{neg}}(f) = \text{DTMIN}_{1-\gamma}(1 - f) \) and \( \text{DTMAX}_{\gamma}^{\text{neg}}(f) = \text{DTMAX}_{1-\gamma}(1 - f) \) so we have

\[ \text{DTMAX}_{\gamma}^{\text{neg}}(f) = 1 - \text{DTMIN}_{\gamma}^{\text{neg}}(1 - f). \]

These elementary aggregations can actually be derived from the ones defined in Section 3 for merging positive ratings. Namely, it is routine to check that the aggregation \( \text{AG}_{\gamma}^{\text{neg}} \) that merges negative ratings with weight distribution \( t \) can be defined as

\[ \text{AG}_{\gamma}^{\text{neg}}(f) = \text{AG}_{1-\gamma}(1 - f). \]

for \( AG \in \{ \text{SLMIN}, \text{SLMAX}, \text{STMIN}, \text{STMAX}, \text{DTMIN}, \text{DTMAX} \} \).

Computing with negative scales mapping to a positive one can thus be achieved by turning the negative scales upside down prior to using a (positive) weighted minimum or maximum.

5.2. Qualitative desintegrals

We now present the generalisation of the previous aggregation schemes that merge negative ratings into a global positive one. We call such generalised aggregations desintegrals.

Here the tolerance level is assigned to sets of criteria by means of an anti-capacity (or anti-fuzzy measure) which is a set function \( \nu : 2^\mathfrak{C} \rightarrow [0,1] \) such that \( \nu(\emptyset) = 1, \nu(\mathfrak{C}) = 0 \), and if \( A \subseteq B \) then \( \nu(B) \leq \nu(A) \). Thus, \( \nu \) is a decreasing set function. The conjugate \( \nu^\star \) of an anti-capacity \( \nu \) is an anti-capacity defined by \( \nu^\star(A) = 1 - \nu(\mathfrak{C} \setminus A) \). Moreover, \( \gamma \) is a capacity if and only if \( 1 - \gamma \) is an anticapacity.

The reason why we are using an anti-capacity is that more impediments lead to downgrading the overall positive score. If \( B \) is a set of impediments and \( \nu(B) \) is the overall score, then \( \nu(B) \) should decrease when \( B \) becomes larger.

A special case of anti-capacity is the guaranteed possibility measure [14] defined by \( \Delta(A) = \bigwedge_{i \in A} t_i \), where \( t \) is a (guaranteed) possibility distribution such that \( \bigwedge_{i} t_i = 0 \). In a multiple criteria perspective, \( t_i \) is the tolerance level of negative criterion \( i \).

In this section integrals are identified with a superscript \( + \) (i.e., \( f_{+}^{\nu} \)) for distinguishing them from desintegrals, identified with a superscript \( - \) (i.e., \( f_{-}^{\nu} \)); moreover the superscript is completed either by "\( \star \)" or "\( \rightarrow \)" depending on whether it is a conjunction-based, or an implication-based expression, since the two types of expression may not coincide. The symbols "\( \star \)" and the "\( \rightarrow \)" are themselves indexed for identifying a particular operator. Qualitative desintegrals can be defined from the corresponding variants of Sugeno integral, by reversing the direction of the local value scales (\( f \) becomes \( 1 - f \)), and by considering a capacity \( 1 - \nu^\star \).
Proposition 11. Fuzzy quantifiers. However, the underlying algebraic structure they consider is the one of MV-algebras (they study Łukasiewicz logic). In this case, we have
\[ \nu^{\text{fuzzy}}(A) = \nu^{\text{MV}}(A), \] where \( \nu^{\text{MV}}(A) \) is the standard membership function of the MV-algebra. This allows us to define fuzzy sets and to study their properties in a more algebraic setting.

We obtain the following desintegrals:

**Definition 2.**
\[ f_{\nu}^{\text{fuzzy}}(A) = \bigwedge_{\mathcal{G}\in\mathcal{A}} \left( 1 - \nu(A) \right) \to \bigvee_{\mathcal{G}\in\mathcal{A}} \left( 1 - f_{\nu}^{\text{fuzzy}}(A) \right). \]

The drastic implicative-based desintegarl can also be expressed using Gödel implication as
\[ f_{\nu}^{\text{fuzzy}, \text{Gödel}}(A) = \bigwedge_{\mathcal{G}\in\mathcal{A}} \left( 1 - \nu(A) \right) \to \bigvee_{\mathcal{G}\in\mathcal{A}} \left( 1 - f_{\nu}^{\text{fuzzy}, \text{Gödel}}(A) \right). \]

First, using Eq. (23) and Proposition 2 (duality property of the integrals) we obtain the following expected duality relation:

**Proposition 10.**
\[ f_{\nu}^{\text{fuzzy}}(A) = 1 - f_{\nu}^{\text{fuzzy}}(A) \text{ where } (\to, \bullet) \in \{(\to, \cdot, \cdot), (\to, \cdot, \cdot), (\to, \cdot, \cdot)\}. \]

When we consider the desintegrals in the context of Sugeno integrals, we observe that the classical desintegrals may not be directly applicable due to the non-monotonic nature of the Sugeno integral. This is in contrast to the fuzzy设置 desintegrals, which are always monotonic.

**Proposition 11.**
\[ f_{\nu}^{\text{fuzzy}, \text{Sugeno}}(A) = \bigwedge_{\mathcal{G}\in\mathcal{A}} \left( 1 - \nu(A) \right) \to \bigvee_{\mathcal{G}\in\mathcal{A}} \left( 1 - f_{\nu}^{\text{fuzzy}, \text{Sugeno}}(A) \right). \]

**Proof.** Let us define \( g = 1 - f \). We have \( g_1 = 1 - f_1 \leq g_2 = 1 - f_2 \leq \cdots \leq g_n = 1 - f_n \) and \( A_f = \{ j \mid g_j \geq g_1 \} = A_{f_1} \leq \cdots \leq A_{f_n} \). So we have the following equalities:

- \( f_{\nu}^{\text{fuzzy}, \text{Sugeno}}(A_f) = \bigwedge_{\mathcal{G}\in\mathcal{A}} \left( 1 - \nu(A_f) \right) \to \bigvee_{\mathcal{G}\in\mathcal{A}} \left( 1 - f_{\nu}^{\text{fuzzy}, \text{Sugeno}}(A_f) \right). \]

Moreover we have the following expressions for the qualitative desintegrals.

**Proposition 12.**
\[ f_{\nu}^{\text{qualitative}}(A) = \bigwedge_{\mathcal{G}\in\mathcal{A}} \left( 1 - \nu(A) \right) \to \bigvee_{\mathcal{G}\in\mathcal{A}} \left( 1 - f_{\nu}^{\text{qualitative}}(A) \right). \]

where \( (\to, \bullet) \in \{(\to, \cdot, \cdot), (\to, \cdot, \cdot), (\to, \cdot, \cdot)\}. \]

**Proof.**
\[ f_{\nu}^{\text{qualitative}}(A) = f_{\nu}^{\text{qualitative}, \text{Gödel}}(A) = \bigwedge_{\mathcal{G}\in\mathcal{A}} \left( 1 - \nu(A) \right) \to \bigvee_{\mathcal{G}\in\mathcal{A}} \left( 1 - f_{\nu}^{\text{qualitative}, \text{Gödel}}(A) \right). \]
We can also compare the desintegrals.

**Proposition 13.** $f_v^{\bullet} \geq f_v^{-\bullet}$ with $(\rightarrow, \star) \in \{(\rightarrow, \bullet), (\rightarrow, \bullet), (\rightarrow, \bullet), (\rightarrow, \bullet)\}$.

**Proof.** $f_v^{\bullet} (f) = f_{1-v}^{-\bullet} (1-f) \geq f_{1-v}^{-\bullet} (1-f) = f_v^{-\bullet} (f)$. □

On this basis we can establish the connection between the desintegrals and the elementary weighted aggregation schemes on negative scales.

**Proposition 14.**

- $f_{\Delta}^{-\bullet} (f) = f_{\Delta}^{-\bullet} (f) = S \min_{\delta} (f)$, $f_{\Delta}^{\rightarrow\Delta} (f) = S \min_{\delta} (f)$ and $f_{\Delta}^{\rightarrow\Delta} (f) = D \min_{\delta} (f)$.
- $f_{\Delta}^{\rightarrow\Delta} (f) = f_{\Delta}^{\rightarrow\Delta} (f) = S \max_{\delta} (f)$, $f_{\Delta}^{\rightarrow\Delta} (f) = S \max_{\delta} (f)$ and $f_{\Delta}^{\rightarrow\Delta} (f) = D \max_{\delta} (f)$, where $\delta (A) = 1 - \Delta (A)$.

**Proof.** We use the relation between the integrals and the desintegrals; and the following remarks: $1 - \Delta$ is a necessity measure, $1 - \nabla$ is a possibility measure. Hence we apply the results proved for the integrals. □

5.3. Desintegrals as upper or lower possibility desintegrals

Just as capacities have possibilistic cores, an anti-capacity $\nu$ has a possibilistic support $\mathcal{S} (\nu)$, defined by $\mathcal{S} (\nu) = \{ \delta : \Delta (A) \leq \nu (A), \forall A \subseteq C \}$ [we keep the same notation $\mathcal{S}$ as in the case of capacities, since there is no risk of confusion]. For each $\nu$, $\mathcal{S} (\nu)$ is a lower semi-lattice which is not empty since there is always at least one guaranteed possibility under any anti-measure based on the following tolerance function $\tau$ expressing complete intolerance: $\forall A \neq \emptyset \subseteq C, t (A) = 0$ and $t (\emptyset) = \nu (\emptyset) = 1$. A result dual of Proposition 1 can then be established.

**Proposition 15.**

$v (A) = \bigvee_{\delta \in \mathcal{S} (\nu)} \Delta (A) = \bigwedge_{\delta \in \mathcal{S} (\nu)} \nabla (A)$.

**Proof.** According to the definition of $\mathcal{S} (\nu)$, $\bigvee_{\delta \in \mathcal{S} (\nu)} \Delta (A) \leq v (A)$ for all $A$.

Let us prove the converse. With the notations used for the capacity in Section 4.4, we define the tolerance level $t_{\nu}^0 (i) = v (C_{\delta})$ for all $i \in C$. Hence the associated guaranteed possibility $\Delta_{\nu}^0 (A)$ belongs to $\mathcal{S} (\nu)$.

Let $A$ be a set of criteria and $C_{\delta}^0$ be the smallest set in the sequence $\{ C_{\delta}^0 \}$ such that $A \subseteq C_{\delta}^0$. By construction we have $i_{\delta} \in A$. The inclusion $A \subseteq C_{\delta}^0$ entails $v (A) \geq v (C_{\delta}^0) = t_{\nu}^0 (i_{\delta})$. Moreover $\Delta_{\nu}^0 (A) = \bigwedge_{\delta \in A_{\nu} (f)} (f) \leq t_{\nu}^0 (i_{\delta}) \leq v (A)$.

When we consider a set of criteria $A$, there exists a permutation $\sigma_{\nu}$ such that $A = C_{\delta_{\nu}}$. Hence, $v (A) = v (C_{\delta_{\nu}}) = t_{\nu}^0 (i_{\nu})$.

Moreover we have $\Delta_{\nu}^{\nu} (A) = t_{\nu}^0 (i) \wedge \cdots \wedge t_{\nu}^0 (n) = v (C_{\delta_{\nu}}) \wedge \cdots \wedge v (C_{\delta_{\nu}}) = v (C_{\delta_{\nu}}) = t_{\nu}^0 (i)$; so $v (A) = \Delta_{\nu}^{\nu} (A)$ and $v (A) \leq \bigvee_{\delta \in \mathcal{S} (\nu)} \Delta (A)$.

Applying the first result to $\nu$ and the relations linking $\Delta$ to $\nabla$ yields the second expression. □

One can restrict the scope of the minimum and that of the maximum to the maximal elements of $\mathcal{S} (\nu)$ using the following proposition.

**Proposition 16.** $\mathcal{S} (\nu) = \{ \delta, \exists_{\sigma}, \delta \leq t_{\nu}^0 \}$ where $t_{\nu}^0 (i) = v (C_{\delta})$ for all $i \in C$.

**Proof.** According to the proof of the previous proposition there exists $\sigma_{\nu}$ such that $v (A) = \Delta_{\nu}^{\nu} (A)$ so $v (A) \leq \bigvee_{\sigma} \Delta_{\nu}^\nu (A)$. Moreover for all permutations $\sigma$, $t_{\nu}^0$ is in $\mathcal{S} (\nu)$ i.e. $\Delta_{\nu}^\nu (A) \leq v (A)$ so $\bigvee_{\sigma} \Delta_{\nu}^\nu (A) \leq v (A)$. Hence $v (A) = \bigvee_{\sigma} \Delta_{\nu}^\nu (A)$ and forall $\delta \in \mathcal{S} (\nu)$, $\exists_{\sigma}$ such that $\delta \leq t_{\nu}^0$. □

Let $\mathcal{S} (\nu)$ be the set of maximal elements in $\mathcal{S} (\nu)$. We have

$v (A) = \bigvee_{\delta \in \mathcal{S} (\nu)} \Delta (A) = \bigwedge_{\delta \in \mathcal{S} (\nu)} \nabla (A)$.

(24)

Hence the following result can be proved:

**Proposition 17.** $f_v^{\bullet} (f) = v_{\delta \in \mathcal{S} (\nu)} (f)$ and $f_v^{\bullet} (f) = \bigwedge_{\delta \in \mathcal{S} (\nu)} f_v^{\bullet} (f)$ where $(\rightarrow, \star) \in \{(\rightarrow, \bullet), (\rightarrow, \bullet), (\rightarrow, \bullet), (\rightarrow, \bullet)\}$.

**Proof.** $f_v^{\bullet} (f) = f_{1-v}^{\bullet} (1-f) = v_{\delta \in \mathcal{S} (\nu)} (1-f) = v_{\delta \in \mathcal{S} (\nu)} (1-f) = v_{\delta \in \mathcal{S} (\nu)} (f) = \bigwedge_{\delta \in \mathcal{S} (\nu)} f_{1-v}^{\bullet} (f)$. $f_v^{\bullet} (f) = f_{1-v}^{\bullet} (1-f) = \bigwedge_{\delta \in \mathcal{S} (\nu)} f_{1-v}^{\bullet} (1-f) = \bigwedge_{\delta \in \mathcal{S} (\nu)} f_{1-v}^{\bullet} (f) = f_{1-v}^{\bullet} (f)$. □
5.4. Potential application

The motivation for desintegrals is decision-making based on bipolar evaluations. An alternative \( f \) is then a vector \((f_1^+, \ldots, f_n^+, f_1^-, \ldots, f_n^-)\) where the \( f_i^+ \) are ratings in a positive scale expressing the strength of the reasons for accepting \( f \) and \( f_i^- \) are ratings in a negative scale expressing the strength of the reasons for rejecting \( f \). The overall evaluation of \( f \) is then expressed by means of qualitative integrals and desintegrals, for instance a pair \((f_1^+, f_1^-)\). See [19] for a discussion and an example of such a bipolar evaluation process.

In order to compare two alternatives, one may either merge the positive evaluations obtained from an integral over positive criteria and from a desintegral with respect to negative ones, or on the contrary handle them separately for making a final comparison of objects. Approaches like cumulative prospect theory follow the first principle, but they are numerical. Approaches proposed by Grabisch [28,29] work with a single qualitative bipolar scale. However the merging of positive and negative values in a finite bipolar scale is problematic [29]. The other principle is more in the spirit of bivariate bipolar approaches to evaluation, leading to a partial preference order, as in [2,7]. However, in this approach criteria are restricted to Boolean valuation scales (all-or-nothing positive or negative criteria) and importance levels bear on single criteria.

The framework presented in this paper opens the way to a generalisation of such qualitative bipolar decision evaluation methods to criteria with more refined value scales and generalised weightings of groups of criteria. For instance, the following is an extension of a Pareto-like decision rule in [2,7]:

\[
f \succeq g \iff f'_v^+ (f^+ \mid g^+) \geq f'_v^+ (g^+) \quad \text{and} \quad f'_v^- (f^- \mid g^-) \geq f'_v^- (g^-) .
\]

Yet another principle for the comparison between two alternatives \( f \) and \( g \) proposed by Bonnfon et al. [2,7] (generalising a proposal of Dubois and Fargier [6]) is that a reason for rejecting \( g \) is viewed as a reason for preferring \( f \):

\[
f \succeq g \iff f'_v^+ (f^+ \mid g^+) \geq f'_v^- (g^- \mid g^- \rightarrow 1 - f'_v^+ (f^+) + f'_v^- (g^- \mid g^- \rightarrow 1 - f'_v^+ (f^+) ) \geq f'_v^- (g^- \mid g^- \rightarrow 1 - f'_v^+ (f^+) ) .
\]

for some suitably chosen operation \( \rightarrow \) (for instance a maximum); moreover note that when moving from \( 1 - f'_v^+ (g^-) \) to \( f'_v^+ (g^-) \), we must swap \( \bullet \) and \( \rightarrow \), after Proposition 10. This expresses that \( f \) is preferred to \( g \) iff the merits of \( f \) together with the defects of \( g \) have more weight than the merits of \( g \) together with the defects of \( f \). Alternatively, one might also consider \( f \succeq g \iff f'_v^- (f^- \mid g^-) \geq f'_v^- (g^-) \geq f'_v^- (g^- \mid g^- \rightarrow 1 - f'_v^+ (f^+) ) , \) reflecting the idea that the defects of \( f \) joined with the merits of \( g \) are less than the defects of \( g \) joined with the merits of \( f \).

6. Conclusion

In this paper, we proposed new variants of Sugeno integral based on the Heyting algebra setting augmented with a Kleene involutive negation. These proposals were motivated by alternative ways of using weights of qualitative criteria in min- and max-based aggregations, that make intuitive sense as tolerance thresholds. We have shown the strong similarity existing between the equivalent expressions of Sugeno integrals and the expressions of our residuation-based integrals. However, in the latter case, the implication-based and conjunction-based expressions are not equivalent, contrary to the case of Sugeno integrals.

The next step is to find characteristic properties of residuation integrals, in the style of existing characterisation of the usual Sugeno integral [35]. First results appear in [22]. It is also of interest to study residuation integrals based on the nilpotent minimum, along with a comparison with the framework proposed in [24,25] that uses Lukasiewicz operations. Indeed, the nilpotent minimum has properties that make it similar to Lukasiewicz conjunction. More generally one may study the minimal properties needed for an implication, in order to preserve all results obtained for Gödel implications and its contrapositive form.

We have also proposed counterparts of Sugeno integral and their variants, for dealing with negative local value scales, we call desintegrals where degrees measure the extent of a defect or penalty. Desintegrals can be expressed in terms of qualitative integrals, which allow us to easily establish their properties. This work paves the way to refined qualitative bipolar decision evaluation methods, where pros and cons (for or against an alternative) can be separately evaluated by means of residuated integrals or desintegrals, when the evaluation process jointly uses dependent positive and negative criteria.
