Selective Electroreduction of Glycerol to 1,2-Propanediol on a Mixed Carbon-Black Activated Carbon Electrode and a Mixed Carbon Black-Diamond Electrode

Ching Shya Lee,* a,b Mohamed Kheireddine Aroua,* c,d Wan Ashri Wan Daud, a Patrick Cognet, b Yolande Pérès, b and Mohammed A. Ajeel e

1,2-propanediol was selectively produced by electroreduction of glycerol in a two-compartment reactor. Two new kinds of cathode electrodes were evaluated: (i) mixed carbon black-activated carbon electrodes and (ii) mixed carbon black-diamond electrodes. These electrodes were compared with a conventional platinum electrode. With a reaction temperature of 80 °C, an electric current of 2.0 A, and ambient pressure, the mixed carbon black-activated carbon electrode demonstrated excellent performance and successfully reduced glycerol to 1,2-propanediol with a high selectivity of 86% and 74% glycerol conversion. The selectivity of 1,2-propanediol on the mixed carbon black-diamond electrode and the platinum electrode was 68% and 61%, respectively, with 88% glycerol conversion on the mixed carbon black-diamond electrode and 67% glycerol conversion on the platinum electrode. The authors propose a possible reaction mechanism for the formation of 1,2-PDO.

Keywords: Electroreduction; Glycerol; 1,2-Propanediol; Activated carbon; Diamond

INTRODUCTION

1,2-Propanediol (1,2-PDO) has a high commercial value of $117/kg (Sigma Aldrich). It is widely used to produce unsaturated polyester resins and antifreeze agent and is used in the cosmetics and food industries (Maris and Davis 2007). The global market of 1,2-PDO is driven by its major applications, particularly in the manufacture of unsaturated polyester resins. Its market price is expected to increase to $4.2 billion/kt by 2019 (Future Market Insights 2016; Markets and Markets 2016). Generally, 1,2-PDO is commercially produced from propylene oxide with water via the hydroperoxide process or the chlorohydrin process (Yadav et al. 2012). Recently, bioglycerol, the byproduct obtained through the transesterification process of biodiesel production, has attracted substantial attention as a renewable feedstock for the synthesis of 1,2-PDO via the catalytic hydrogenolysis pathway.

Previous studies demonstrated the effectiveness of various catalyst systems in glycerol hydrogenolysis. These systems combine noble metals including Ru, Pd, Rh, and Pt with other transition metals such as Zn, Cr, and Cu with silica, zeolite, aluminium
oxide, or activated carbon supports (Rode et al. 2010). Kusunoki et al. (2005) reported that an Ru/C catalyst converted 79% glycerol to 1,2-PDO with a selectivity of 82% under the reaction conditions of 120°C and 4 MPa H2 pressure for 10 h in the presence of Amberlyst-15. However, Ru alone could effectively enhance the byproduct reaction by cracking glycerol into smaller compounds such as ethylene glycol, ethanol, methanol, and methane (Kusunoki et al. 2005). Maris et al. (2007) indicated that hydrogenolysis on Pt or bimetallic Pt/Ru supported by C resulted in high selectivity for lactate rather than 1,2-PDO at high pH or in the presence of base (Maris and Davis 2007). In the catalytic process, reactions are usually conducted under high temperature and high pressure conditions. As such, the cost of production is high due to high energy usage. The reaction conditions, types of catalysts, glycerol conversion percentages, and selectivity for 1,2-PDO are summarized in Table 1.

T, reaction temperature; P H2, hydrogen pressure; Y, yield; S, selectivity

Electrolysis is an alternative pathway to overcome the shortcomings of current methods. This method is simple, robust, and can operate under ambient pressure and low reaction temperature. In previous studies, the electrochemical conversion of glycerol has been based on electro-oxidation. However, the study of the electroreduction of glycerol into 1,2-PDO has not been reported previously. Glycerol can be electro-oxidised into
various hydroxyl acids such as glycolic acid, mesoxalic acid, and glyceric acid (Simões et al. 2010, 2011; Zhang et al. 2014). The selectivity of these products is dependent on the pH of the reaction medium and the type of electrode materials (Avramov-Ivić et al. 1991, 1993; Roquet et al. 1994; Yildiz and Kadirgan 1994).

Activated carbon, which is commonly functionalized with polymer or incorporated with noble metals such as Pt, Pd, Rh, and Au, is broadly used as an electrode in electrochemical studies (Card et al. 1990; Bambagioni et al. 2009; Kwon et al. 2012). Activated carbon with a high specific surface area (1000 m²/g) can be produced from readily available biomass precursors such as coal, coke, saw dust, peat, wood char, seed hulls, and palm kernel shell (Omar et al. 2003; Kalderis et al. 2008; Foo and Hameed 2011; Elmouwahidi et al. 2012; Foo and Hameed 2013; He et al. 2013; Lee et al. 2013). The large surface area and pore size of the carbon support can improve ion transport and electrolyte accessibility (Tang et al. 2013).

Another material which is currently widely used in the electrochemical study is doped diamond electrode. In the study by Kraft (2007), doped diamond electrode was compared with platinum electrode in the region between oxygen and hydrogen evolution in 0.2 M H₂SO₄ by using cyclic voltammetry. The result obtained shows that doped diamond electrode has a wider potential window and high oxygen as well as hydrogen evolution overpotential (Kraft 2007). This striking feature distinguishes the doped diamond electrode from common electrode materials, such as Pt, Au, or mixed metal electrodes. The doped diamond electrode demonstrates high electrochemical stability under severe conditions (Panizza and Cerisola 2005; Alfaro et al. 2006). However, the surface area of doped diamond electrode is restricted by the size of chemical vapor deposition chamber.

A carbon black diamond (CBD) composite electrode, which has no limitation on the shape and dimension, was investigated for the first time in our laboratory for electrochemical oxidation of organic pollutants, such as phenol and benzoquinone. The CBD electrode offered a wide potential window and inert surface. Its potential window decreased with increasing of carbon black (CB) percentage in the electrode. The 5% CB presented a similar potential window as the conventional boron doped diamond electrode (Ajeel et al. 2015c). However, results reported that 20% CBD electrode achieved a high removal efficiency (96.5%) for benzoquinone (200 g/L) after 20 min of oxidation (Ajeel et al. 2015b). In addition, CBD electrode showed a high selectivity in phenol oxidation in comparison with the conventional Pt electrode, whereby fumaric acid was the only chemical compound observed after the electro-oxidation process (Ajeel et al. 2015c). Later, an activated carbon composite (ACC) electrode was prepared and used as anode electrode for 2-chlorophenol electro-oxidation. The performance of ACC was compared with CBD (20% CB). After 6 h of electro-oxidation, the degradation efficiencies of ACC and CBD on 2-chlorophenol were 82.5% and 96.0%, respectively. ACC offered higher surface area by fourfold compared to that of CBD, and it exhibited the same degradation rate as the CBD electrode (Ajeel et al. 2015a). Moreover, the price of activated carbon and diamond materials are lower than that of noble metal catalysts (Pt, Pd, Rh, and Au). The cost of each material per gram is displayed in Table 2 (Sigma Aldrich). Due to their high selectivity and cost effectiveness advantages, two environmentally friendly, low-cost carbon-based electrodes (mixed carbon black-activated carbon electrodes (CBAC) and mixed carbon black-diamond (CBD) electrodes) are proposed in the present study.

*in nanopowder form
**in powder form

In this work, 20% CBAC and 20% CBD were prepared and used as the cathode electrode for electrochemical conversion of glycerol. The electrochemical conversion was carried out in a two-compartment electrochemical cell to avoid the mixed oxidation-reduction process that occurs in a single-compartment electrochemical cell (Saila et al. 2015). Hence, enhanced selectivity to 1,2-PDO was expected. The glycerol conversion and product selectivity were compared with those obtained using the conventional Pt electrode. A potential reaction mechanism is proposed.

EXPERIMENTAL

Electrode Preparation

A CBAC electrode (with a geometrical surface area of 14 cm$^2$) was prepared by mixing 80 wt.% activated carbon powder (AC) (99.5% purity with an average particle size of 100 µm and a 950 m$^2$/g specific surface area) (Sigma Aldrich, Germany) and 20 wt.% carbon black nanopowder (CB) (99% purity with an average particle size of 13 nm and a 550 m$^2$/g specific surface area) (Alfa-chemicals, United Kingdom) to a total weight of 3.0 g. The CBD electrode (with a geometrical surface area of 14 cm$^2$) was prepared by blending 20 wt.% CB nanopowder and 80 wt.% nanodiamond powder (98.3% purity with an average particle size of 3 nm to 10 nm and a 200 m$^2$/g to 400 m$^2$/g specific surface area) (Sigma Aldrich). CB nanopowder was added during the electrode preparation to increase the conductivity of the electrode (Ajeel et al. 2015c). The ratio of each composition used in the electrode preparation was described in an earlier study on the electro-degradation of 2-chlorophenol. Ajeel (et al. 2015a) reported that the AC and diamond electrodes with 20 wt.% CB nanopowder had a removal efficiency of 2-chlorophenol as high as 83% and 96%, respectively. Therefore, a similar electrode was prepared and used as a cathode electrode in this study.

The pre-mixed powder was added into a mixture containing 20% v/v of polytetrafluoroethylene and 80% v/v of 1,3-propanediol to obtain a powder-to-liquid ratio of 1:2. The slurry was pressed neatly and oven dried in accordance with the following heating temperature program: 100 °C for 2 h, 180 °C for 1 h, 250 °C for 1 h, and 350 °C for 30 min to allow complete sintering of the powder and increase electrode hardness (Ajeel et al. 2015a).

Scanning Electron Microscopy (SEM)

The morphology of the CBAC and CBD electrodes were studied by scanning electron microscopy using a Hitachi SU-8000 instrument (Tokyo, Japan) equipped with
an energy dispersive X-ray (EDX) analyser. The element content in the electrode was determined by EDX.

**Measurement of Active Surface Area**

The active surface areas of CBAC and CBD electrodes (with geometrical surface areas of 0.45 cm$^2$) were measured by chronoamperometry analysis in 0.005 M ferrocyanide solution (K$_4$Fe(CN)$_6$ ($\geq$ 99.95% purity) (Sigma Aldrich) containing 0.1 M KH$_2$PO$_4$ (purity $\geq$ 99%) (Sigma Aldrich). The test was performed with an Autolab Potentiostat from Metrohm (Model PGSTAT101, Switzerland). The active surface areas of the CBAC and CBD electrodes were obtained using the Cottrell equation (Ajeel et al. 2015a),

$$I = \frac{nFAD^{1/2}C_0}{\pi^{1/2}t^{1/2}}$$

(1)

where $I$ is the current (A), $n$ is the number of electrons, $A$ is the active surface area of the electrode (cm$^2$), $D$ is the diffusion coefficient ($6.20 \times 10^{-6}$ cm$^2$/s), $C_0$ is the bulk concentration of K$_4$Fe(CN)$_6$ (mol/cm$^3$), $F$ is the Faraday constant 96487 (C/mol), and $t$ is the time (s).

**Electrochemical Reduction Behavior**

The electroreduction of glycerol was carried out in a two-compartment reactor separated by a cation exchange membrane (Nafion-117, Fuel Cell Store, United States), as shown in Fig. 1. Each compartment was filled with 0.25 L of 0.30 M glycerol solution. Next, 24.0 g of Amberlyst-15 and 10.0 g of Na$_2$SO$_4$ were dispersed into the entire glycerol solutions. Amberlyst-15 was used as an acid catalyst in this study. The strong sulfonic acid group in Amberlyst-15 allows it to serve as an excellent catalyst during the electrolysis performance. The application of Amberlyst-15 in the electrochemical conversion of glycerol was previously studied by the author and was found that the presence of Amberlyst-15 can enhance the glycerol conversion, product selectivity and yield.

Pt (geometrical surface area of 22 cm$^2$) was used as the anode electrode. Three types of cathode materials were studied: Pt (geometrical surface area of 33.0 cm$^2$), CBAC (geometrical surface area of 14.1 cm$^2$), and CBD (geometrical surface area of 14.1 cm$^2$). A constant current (2.0 A) was supplied to the system, and the reaction temperature was controlled at 80 °C for 8 h.
Product Characterization and Quantification

The products were separated and characterized by gas chromatography-mass spectroscopy (GC-MS) (Agilent Model 7890, United State) with an attached ZB-Wax column (30 m × 0.25 mm × 0.25 µm). High purity helium (> 99.99%) was used as the carrier gas at a constant flow of 2.0 mL min\(^{-1}\). The initial oven temperature was set to 45 °C, maintained for 5 min, and then increased at a rate of 10 °C min\(^{-1}\) to reach the final temperature of 240 °C, which was maintained for 5 min. The injection volume was 1 µL. The results were compared with the chemical standards and MS library (ChemStation software) (Agilent). The glycerol conversion and selectivity were calculated by Eqs. 2 and 3, respectively.

\[
\text{Glycerol conversion (\%)} = \frac{\text{Amount of glycerol converted (in mole C)}}{\text{Total amount of glycerol in reactant (in mole C)}} \times 100 \%
\]

(2)

\[
\text{Product selectivity (\%)} = \frac{\text{Amount of product (in mole C)}}{\text{Sum of all products (in mole C) in liquid phase}} \times 100 \%
\]

(3)

RESULTS AND DISCUSSION

CBAC and CBD Electrode Characterization

Scanning electron microscopy was used to investigate the morphologies of the CBAC and CBD electrodes. Scans were performed at high magnification (50000×) with image resolutions of 1.00 µm. The SEM image for the CBAC electrode in Fig. 2a shows that CBAC exhibited high porosity with average pore sizes ranging from 90 nm to 170 nm. The detectable pore sizes for the CBD electrode were smaller (around 14 nm to 22
nm) (Fig. 2b) and lower than those of the CBAC electrode. The mesoporous and macroporous structure in both electrodes can help to hold or trap the reaction intermediate, thus enhancing the product selectivity (Qi et al. 2014; Zhang et al. 2014).

Fig. 2. SEM images of (a) CBAC and (b) CBD electrodes

The elements present in the electrodes were determined using SEM-EDX, and the spectra for the CBAC and CBD electrodes are shown in Fig. 3a and Fig. 3b, respectively. The CBAC electrode contained three elements, namely carbon (C), fluorine (F), and oxygen (O). Carbon was the major element in the CBAC electrode, with a nominal value of 75 wt.%. Fluorine and O could be the elements from the binder and solvent (polytetrafluoroethylene and 1,3-propanediol) used in the electrode preparation with corresponding values of 21 wt.% and 4% wt.%, respectively. The CBD electrode contained the same elements, namely C (92 wt.%), F (6 wt.%), and O (1 wt.%).

Fig. 3. SEM-EDX spectrum for (a) CBAC and (b) CBD electrodes

Cathodic Reduction Behavior of Glycerol on the CBAC and CBD Electrodes

Prior to the electrochemical study, the electroreduction behavior of glycerol was examined on the CBAC and CBD electrodes by CV analysis in the presence of Amberlyst-15. Blank CVs without glycerol were prepared on the CBAC and CBD electrodes. Scanning was performed from +0.05 V to -1.80 V at a scan rate of 0.2 V s\(^{-1}\). Figure 4 shows the cyclic voltammogram of the CBAC and CBD electrodes. Compared with the CVs in the absence of glycerol, no obvious cathodic peaks were observed on either electrode in the presence of glycerol. These results might have been due to the lack of direct electron transfer with glycerol on the CBAC and CBD electrodes during the electroreduction process. The electroreduction of glycerol might have occurred indirectly.
Despite the absence of reduction peaks for glycerol on the CBAC and CBD electrodes, the cathodic current slightly increased for the glycerol solution, showing that electroreduction on the CBAC and CBD electrodes was favourable in the presence of glycerol.

**Fig. 4.** CV of CBAC and CBD electrodes in blank solution and aqueous solution of glycerol in the presence of Amberlyst-15 with a scan range from +0.05 to -1.80 V and a scan rate of 0.2 V/s

### Electroreduction of Glycerol to 1,2-PDO

The electroreduction of glycerol was performed in the presence of Amberlyst-15, at a temperature of 80 °C, and an electric current of 2.0 A over the CBAC and CBD electrodes. The results were then compared with those of the Pt electrode, as shown in Fig. 5. Glycerol was converted to 67%, 74%, and 88% on the Pt, CBAC, and CBD cathodes, respectively. The first-order kinetic models for the reaction over the Pt, CBAC, and CBD electrodes are shown in Fig. 6. In agreement with Kongjao et al. (2011), the electrolysis on the Pt electrode only fit the first-order kinetic model well at 2 h. The rate constants on the Pt, CBAC, and CBD electrodes were 0.191 h⁻¹, 0.165 h⁻¹, and 0.197 h⁻¹, respectively.

**Fig. 5.** Glycerol conversion profile through the electroreduction of glycerol in the presence of Amberlyst-15 at 2.0 A and 80 °C over Pt, CBAC, and CBD cathode electrodes.
According to the GC-MS chromatogram in Fig. 7, 1,2-PDO, acetol, and diethylene glycol (DEG) were found in all samples. In the presence of H⁺ ions supplied by Amberlyst-15, glycerol was first dehydrated into acetol (Ishiyama et al. 2013). In the catalytic hydrogenolysis pathway, acetol was further reduced to 1,2-PDO (Chaminand et al. 2004; Huang et al. 2009). This phenomenon could explain the absence of reduction peaks in the CV analysis as the glycerol underwent indirect electroreduction. During electrolysis, the reduction compound 1,2-PDO was produced through the electroreduction of the intermediate (acetol) instead of the direct reduction of glycerol. Ethylene glycol was produced via C-C bond cleavage during the reduction process (Nakagawa and Tomishige 2011). Diethylene glycol is formed by the coupling of ethylene glycols.
Fig. 8. Proposed reaction mechanism for the electroreduction of glycerol

Although DEG was obtained as a side product in this study, it is also a valuable glycerol derivative. Compared with the price of crude glycol, the market value for DEG is significantly higher at $134/kg (Sigma Aldrich). The reaction mechanism is proposed in Fig. 8.

In the initial stage of the reaction, 1,2-PDO was not detected in any specimen. After 1 h, 2 h, and 3 h of electrolysis, 1,2-PDO was observed in small amounts on the CBAC, Pt, and CBD electrodes, respectively. The highest product selectivity for 1,2-PDO (86%) was obtained on the CBAC electrode with 74% glycerol conversion after 8 h. Acetol and DEG were also obtained in the reaction mixture with a total selectivity of 14%. Based on the product selectivity graph in Fig. 9, the reduction performances on the Pt and CBD electrodes were slightly lower compared with the CBAC electrode. The 1,2-PDO selectivity of 61% (on Pt) and 68% (on CBD) were obtained after 8 h of reaction time. SEM analysis demonstrated that the surface of the CBAC electrode had high porosity with larger pore sizes than the CBD electrode. This result indicated that the CBAC electrode had higher active surface areas and larger pore sizes than those of the CBD and Pt electrodes. The diffusion limit of the substrates can be reduced when the pores size increase, thus improving ion transport during electrolysis and increasing the product selectivity as well as glycerol conversion (McMorn et al. 1999).
The chronoamperometry analysis revealed that the CBAC and CBD electrodes with the same geometrical surface area of 14 cm$^2$ had active surface areas of 227 cm$^2$ and 88 cm$^2$, respectively. The Pt electrode (geometrical surface area of 33 cm$^2$) had an active surface area of only 43 cm$^2$. The high active surface area of the CBAC electrode improved the electrocatalytic activity by increasing electrolyte accessibility and improving ion transportation (Tang et al. 2013). Table 3 summarizes the product selectivity and glycerol conversion on the Pt, CBAC, and CBD electrodes.

Research Outlook

Based on results obtained in prior studies (Table 1), this study led to a comparable or better selectivity for 1,2-PDO under milder reaction conditions. Electrolysis was performed at ambient pressure and a reaction temperature of 80 °C. Moreover, peak selectivity for 1,2-PDO was achieved after 8 h of electrolysis time. Shortening the reaction time can reduce the contact time of glycerol with the electrocatalyst, thereby stopping the production of unfavorable byproducts. When glycerol reacts under high reaction temperature and pressure for many hours, the glycerol C-C bond breaks, which leads to further formation of small unwanted compounds such as ethylene glycol (Rode et al. 2010). This study also showed that fewer compounds were formed during electrolysis than during the fermentation process.

In addition, the price of the electrode materials must be inexpensive to compete effectively with the current available catalyst and electrocatalyst. Based on the costs...
shown in Table 2, the CBAC and CBD electrodes are relatively cheap compared with noble metal catalysts (Pt, Pd, Rh, and Ru). Furthermore, AC can be easily obtained from biomass feedstocks such as saw dust, seed hulls, and palm kernel shell. In Malaysia, palm kernel shell is the main source for AC because it is one of the most prominent agricultural wastes obtained from the oil palm industry (Abdullah et al. 2011).

CONCLUSIONS

1. In this study, the direct electroreduction of glycerol was examined. Glycerol was successfully reduced to 1,2-PDO on the two new cathode materials of CBAC and CBD.
2. The highest 1,2-PDO selectivity of 86% was obtained after 8 h of reaction time with a maximum glycerol conversion of 74% occurring on the CBAC electrode.
3. On the CBD electrode, the glycerol conversion percentage was 88% with a 1,2-PDO selectivity of 68%.
4. Acetol and DEG were also obtained, but in very low product selectivity.
5. These findings successfully provided a new approach for glycerol electroreduction studies.
