Abstract: Spike-and-wave discharge (SWD) pattern detection in electroencephalography (EEG) is a crucial signal processing problem in epilepsy applications. It is particularly important for overcoming time-consuming, difficult, and error-prone manual analysis of long-term EEG recordings. This paper presents a new method to detect SWD, with a low computational complexity making it easily trained with data from standard medical protocols. Precisely, EEG signals are divided into time segments for which the continuous Morlet 1-D wavelet decomposition is computed. The generalized Gaussian distribution (GGD) is fitted to the resulting coefficients and their variance and median are calculated. Next, a k -nearest neighbors (k -NN) classifier is trained to detect the spike-and-wave patterns, using the scale parameter of the GGD in addition to the variance and the median. Experiments were conducted using EEG signals from six human patients. Precisely, 106 spike-and-wave and 106 non-spike-and-wave signals were used for training, and 96 other segments for testing. The proposed SWD classification method achieved 95% sensitivity (True positive rate), 87% specificity (True Negative Rate), and 92% accuracy. These promising results set the path for new research to study the causes underlying the so-called absence epilepsy in long-term EEG recordings.

Keywords: spike-and-wave; generalized Gaussian distribution; EEG; Morlet wavelet; k -nearest neighbors classifier; epilepsy

1. Introduction

Epilepsy is a chronic neurological disorder that affects patients, causing recurrent seizures. Seizures are characterized by excessive electrical discharges in neurons. Their waveform, known as the spike, is characterized by brief bursts of high amplitude, synchronized and multiphasic activity with several polarity changes [1]. These are exhibited close to the epileptic focus and stand out from the background EEG activity. Electroencephalography (EEG) is currently the main technique to record electrical activity in the brain. Neurologists, trained in EEG, are able to properly determine an epilepsy diagnosis by analyzing the different types of spikes in the so-called rhythmic activity of the brain.

Existing, automatic methods for detecting epileptic events in EEG signals have performance that greatly exceed visual inspection. These methods focus mostly on interictal spikes [2,3], seizure onset detection [4], or waveform epileptic patterns [5,6]. There exists a wide variety of methods to accurately detect seizures and their patterns in EEG. Most of these methods are based on supervised

machine learning techniques, such as Support Vector Machine [7], logistic regression [8], decision trees [9], k -Nearest Neighbor, Random Forest [10], or discriminant analysis [11]. They mainly differ according to their feature extraction and classification approaches. A large variety of features are used, including spatio-temporal analysis [12], spectral-temporal analysis [13], wavelet decomposition [2], spectrogram [14,15], Hilbert transform [16], neural networks [17], Hurst exponent [18], quadratic linear-parabolic model [19], and statistical descriptors such as statistical modeling [20], signal fuzzy entropy [21], and fractal dimension [22]. The reader is referred to [23] for a recent state-of-the-art on methods for seizure detection in EEG.

Spike-and-wave discharge (SWD) is a generalized EEG discharge pattern, where the waveform has a regular and symmetric morphology. This morphology can be mathematically described by a Morlet wavelet transform, generating a time-frequency representation of the EEG signal [24–27]. The spike component of an SWD is associated with neuronal firing and the wave component is associated with neuronal inhibition or hyperpolarization of neurons [28]. SWD is widely used in mice studies [2,14,29,30]; inversely, the literature reports very limited human applications. Mice have a predisposition for generalized SWD at 7–12 Hz [15]. Typically, they have spontaneous absence-seizure-like events, but, the presence of an intact cortex, thalamus, and their interconnections are necessary to record their signals [31,32]. Rodent models are usually used to study the neurobiological mechanisms underlying SWD in humans. However, studies in humans and rodents differ in the way SWD is assessed and, more importantly, rodents and humans show substantial biological differences. Thus, more human studies are necessary to fully understand this phenomena. This paper fits in this general aim by studying SWD in human.

Some recent works have been proposed to estimate SWD patterns in humans using machine learning techniques. They rely on different models and features, including 1-NN with t-location-scale distribution [20], decision-trees with cross-correlation coupled with decision trees [9], and Bayesian classifiers with the Walsh transformation [33]. Table 1 lists some more methods. Other existing methods implement signal analysis techniques, such as Hilbert–Huang transform to analyze time-frequency energy distribution [34], complex network of neuronal oscillators to model SWD [35], analyzing statistical features such as variance, the sum of wave amplitudes, slope of the wave [36], or topographic cluster analysis based on connectivity, entropy, frequency, power, and spike amplitude [37]. For a biological dynamic explanation of features and mechanisms generating SWD in the brain see [38].

Table 1. Some state-of-the-art methods for the spike-and-wave discharge (SWD) estimation in electroencephalography (EEG) signals in humans, compared in terms of classification techniques, features, and reported performance. Abbreviations are as follows: high Specificity, rule in (SpPIn), According to the frequency and magnitude weighted average (WA), According to an estimated threshold (AET).

| Method | Features | Classifier | Accuracy in % | Ref. |
|---|--|----------------|---------------|------|
| Generalized Gaussian distribution (GGD) | GGD parameters, variance and median from time-frequency Morlet decomposition | 10-NN | 92 | our |

| Cross-correlation | Wavelet spectrum correlation | AET | 100 | [41] |

This paper presents a new SWD patient-specific detection method based on the statistical modeling of the continuous Morlet wavelet coefficients. Precisely, we fit the generalized Gaussian distribution to these coefficients and estimate the corresponding parameters. These parameters are used as features in a 10-NN classifier. Training and testing of the learning model use different EEG datasets.

The remainder of the paper is structured as follows. Section 2 presents the EEG database, and the proposed methodology, where we explain the continuous Morlet wavelet transformation,

the generalized Gaussian distribution (GGD) statistical model, and the k -NN classifier. Experimental results using the scale parameter from the GGD and the variance and median from the continuous wavelet coefficients are reported in Section 3, followed by discussion in Section 4. Conclusions, remarks, and perspectives are presented in Section 5.

2. Materials and Methods

This section presents our statistical model-based method to detect spike-and-wave discharges (SWD) in EEG signals. It is computationally very efficient, suitable for real-time implementation, allowing on-line spike-and-wave detection. First, we describe the dataset used for experimentation, then we present the different processing steps.

2.1. Database

A standard 10/20 EEG system was used at the Foundation for the Fight against Pediatric Neurological Disease (FLENI) to acquire long-term 256 Hz EEG signal, from 12 human patients. The following 22-channels were used: Fp1, Fp2, F7, F3, Fz, F4, F8, T3, C3, Cz, C4, T4, T5, P3, Pz, P4, T6, O1, O2, Oz, FT10 and FT9. See [39] for more details. The acquired signals had a different waveform and duration.

All EEG signals were labeled by a neurologist from FLENI to indicate the onset and duration of the epilepticform. Based on these annotations, we extracted 212 short epochs (1-min average duration) focusing on the spike-and-wave waveform. As such, a database with the 212 monopolar signal epochs was created, with 106 SWD signals and 106 non-SWD signals. Each SWD signal has been restricted to a narrow frequency band between 1–3 Hz. Figure 1 shows an example of a typical SWD signal. Visually, one can observe that SWD patterns exhibit characteristic morphology; whereas non-SWD signals have normal waveform.

Six patients with twenty (20) signals each were used for training our predictive model (Section 2.2). This multiplicity of signals from the same patient has been decided to enforce learning-patient specific patterns. A set of 96 signals from the other six patients were used for testing.

Figure 1. (a) A sample SWD signal and the Morlet wavelet. Note that the scales are different. (b) Example of 6 channels of one monopolar raw EEG, with SWD patterns in all channels.

2.2. Methodology

The proposed method is composed of four stages. The first stage divides every EEG signal epoch, $\mathbf{X} \in \mathbb{R}^{N \times M}$ with M channels and N time instants, into two-second segments per channel, with one-second overlap across a rectangular sliding window. Please note that M is fixed to 22, whereas N varies for different epochs (with an average duration of 60 s giving about $N = 256 * 60 = 15,360$ samples). This will give $\lfloor N/60 \rfloor$ segments per channel. The second stage consists of applying Morlet decomposition to create separate time–frequency representations for each segment $\mathbf{X}_t \in \mathbb{R}^{N \times 1}$. The purpose of this decomposition is to evaluate the energy distribution throughout the SWD frequency band (1–3 Hz). In the third stage, the statistical distribution of the wavelet coefficients from each segment is represented using a zero-mean generalized Gaussian distribution (GGD). A maximum likelihood method is used to estimate the GGD parameters, *scale* (ζ) and *shape* (τ) [4,42–44]. This statistical modeling stage gives $M \times \lfloor N/60 \rfloor$ pairs of *scale* (ζ) and *shape* (τ) parameters, achieving a very strong dimension reduction. As we demonstrate it in the experimentation section, the scale parameter ζ was found statistically characteristic of the SWD waveform, and it is proposed as a feature to detect such patterns [4,44]. Using a single parameter to classify patterns is too strict and misses the natural variability in the data. For this reason, we compute two other statistical parameters, namely the variance (σ^2) and the median (\tilde{x}) from the wavelet coefficients of each segment. The data from one EEG epoch reduces therefore to three parameters, $\{\zeta, \sigma^2, \tilde{x}\}$, giving a high dimension reduction while offering a flexible representation space to discriminate patterns while accounting for natural variability. Please note, in total, we will have $M \times \lfloor N/60 \rfloor * 3$ parameters for any EEG signal epoch. Finally, a classification model has been trained to detect SWD patterns, using the three features parameters. The proposed methodology is summarized in Figure 2. The following sections describe each stage.

We now introduce the Morlet wavelet, the Generalized Gaussian distribution, and the k-nearest neighbor classifier used in this paper.

Figure 2. Diagram of the proposed method.

2.2.1. Morlet Wavelet

The continuous wavelet transform is given by

$$W_f(t, a, b) = \int_{-\infty}^{\infty} X_t \psi_{a,b}^*(t) dt \quad (1)$$

$$\psi_{a,b}^*(t) = \frac{1}{\sqrt{a}} \psi \left(\frac{t-b}{a} \right) \quad (2)$$

$$\psi(t) = \exp^{-\frac{t^2}{2}} \cos(5t) \quad (3)$$

where a is the scaling parameter and b the shift parameter. Equation (2) is the mother wavelet function, where $(*)$ denotes the complex conjugate operation. Equation (3) is the analytic expression of the Morlet wavelet [45]. In order to use the Morlet wavelet with frequency f_c , we use the relationship

$$f_a = \frac{f_c}{\alpha \Delta} \quad (4)$$

where α is the scale, Δ is the sampling period, f_c is the center frequency of Morlet wavelet (in Hz) and f_a is the pseudo-frequency corresponding to the scale a (in Hz). As such, the wavelet dominant frequency can be characterized using the center frequency, as it detects the main wavelet oscillations (the reader is referred to [46] for details). Note that the wavelet scale is estimated according to the narrow frequency 1–3 Hz from (Section 2.1). In our case, $\Delta = 256$, and $1 < \text{frequency} < 3$, we have a scale $\alpha \in f_c * \Delta, f_c * \Delta / 3$. Figure 3 show an example of time-scale variation for a value of $f_c = 1.2308$ for SWD and $f_c = 0.8125$ for non-SWD. These data are from signal 1 from patient 1.

2.2.2. Generalized Gaussian Distribution

The generalized Gaussian distribution (GGD) is a flexible statistical model often used in science and engineering to represent data. We propose to represent the distribution of the Morlet wavelet coefficients (C_t) using the GGD [47]. The probability density function (PDF) of the GGD is given by the expression

$$f_{\text{GGD}}(x; \zeta, \tau) = \frac{\tau}{2\zeta\Gamma(\tau^{-1})} \exp\left(-\left|\frac{x}{\zeta}\right|^\tau\right) \quad (5)$$

where $\zeta \in \mathbb{R}^+$ is a scale parameter, $\tau \in \mathbb{R}^+$ is a shape parameter, and $\Gamma(\cdot)$ is the Gamma function. Fitting equation (5) to the data C_t is performed using the maximum likelihood estimators $\Theta_{C_t}^1$:

$$\Theta_{C_t}^1 = [\zeta_t, \tau_t]^T = \arg \max_{[\zeta, \tau]^T} f_{\text{GGD}}(C_t; \zeta, \tau) \quad (6)$$

For more details about the estimation of the GGD parameters, we refer the reader to our previous work [4,42–44,48].

2.2.3. Feature Parameters

Through the previously-described stages, data from every signal epoch, $M \times N$ samples, is reduced to the matrix of parameters (or features) Θ_{C_t} , composed of $M \times [N/60]$ rows, with three columns consisting of our data, reduced to the matrix of parameters (or features) Θ_{C_t} , composed of the scale parameter from the GGD, the variance and the median of the Morlet wavelet coefficients.

$$\Theta_{C_t} = [\zeta_t, \sigma_t^2, \tilde{x}_t]. \quad (7)$$

Using this representation, the next stage consists of training a k -nearest neighbors classifier to detect SWD patterns. Please, recall that we have 212 signal epochs in our database. All went through the preceding dimension reduction process. A set of 120 of those (from six patients) served for training and the remaining 96 (from the six other patients) were used for testing.

Figure 3. Illustration of the variation of time-scale for Morlet continuous wavelet (a) for SWD with $f_c = 1.2308$ Hz, and (b) for non-SWD with $f_c = 0.8125$. Note that, the energy distribution pattern is different when comparing SWD and non-SWD.

2.2.4. k -Nearest Neighbors Classification

Using the feature vector Θ_{C_t} , consider a classification into two possible classes $c = 0$ (non-SWD) and $c = 1$ (SWD). The probability of classifying a sample in one of the two classes is given by

$$\begin{aligned} \rho(\Theta_{C_t} | c = 0) &= \frac{1}{N_0} \sum_{n \in \text{class } 0} \mathcal{N}(\Theta_{C_t} | \Theta_{C_t}^n, \sigma^2 I) \\ &= \frac{1}{N_0 (2\pi\sigma^2)^{D/2}} \sum_{n \in \text{class } 0} \exp^{-\frac{(\Theta_{C_t} - \Theta_{C_t}^n)^2}{2\sigma^2}} \end{aligned} \quad (8)$$

$$\begin{aligned} \rho(\Theta_{C_t} | c = 1) &= \frac{1}{N_1} \sum_{n \in \text{class } 1} \mathcal{N}(\Theta_{C_t} | \Theta_{C_t}^n, \sigma^2 I) \\ &= \frac{1}{N_1 (2\pi\sigma^2)^{D/2}} \sum_{n \in \text{class } 1} \exp^{-\frac{(\Theta_{C_t} - \Theta_{C_t}^n)^2}{2\sigma^2}}, \end{aligned} \quad (9)$$

where D is the dimension of the sample Θ_{C_t} , N_0 and N_1 are the numbers of training samples from class 0 and class 1, respectively; and σ^2 is the variance. Using the Bayes rule to classify a new observation $\Theta_{C_t}^*$, we obtain the following equation

$$\rho(c = 0 | \Theta_{C_t}^*) = \frac{\rho(\Theta_{C_t}^* | c = 0) \rho(c = 0)}{\rho(\Theta_{C_t}^* | c = 0) \rho(c = 0) + \rho(\Theta_{C_t}^* | c = 1) \rho(c = 1)} \quad (10)$$

The maximum likelihood gives $\rho(c = 0) = N_0 / (N_0 + N_1)$, and $\rho(c = 1) = N_1 / (N_0 + N_1)$. Substituting in Equation (10), we obtain the probability $\rho(c = 0 | \Theta_{C_t}^*)$. The expression for $\rho(c = 1 | \Theta_{C_t}^*)$ can be

derived in a similar manner. To determine which class is most likely, the ratio between the two expressions is evaluated

$$\frac{\rho(c=0|\Theta_{C_t}^*)}{\rho(c=1|\Theta_{C_t}^*)} = \frac{\rho(\Theta_{C_t}^*|c=0)\rho(c=0)}{\rho(\Theta_{C_t}^*|c=1)\rho(c=1)} \quad (11)$$

If the ratio is greater than one, $\Theta_{C_t}^*$ is classified as $c=0$, otherwise it is classified as $c=1$. It is important to note that in the case where σ^2 is very small in (11), then both the numerator and denominator will be dominated by the term for which the sample $\Theta_{C_t}^{n_0}$ in class-0 or $\Theta_{C_t}^{n_1}$ in class-1 are closest to the point $\Theta_{C_t}^*$, such that

$$\begin{aligned} \frac{\rho(c=0|\Theta_{C_t}^*)}{\rho(c=1|\Theta_{C_t}^*)} &= \frac{\exp\left[-\frac{(\Theta_{C_t}^* - \Theta_{C_t}^{n_0})^2}{2\sigma^2}\right] \rho(c=0)/N_0}{\exp\left[-\frac{(\Theta_{C_t}^* - \Theta_{C_t}^{n_1})^2}{2\sigma^2}\right] \rho(c=1)/N_1} \\ &= \frac{\exp\left[-\frac{(\Theta_{C_t}^* - \Theta_{C_t}^{n_0})^2}{2\sigma^2}\right]}{\exp\left[-\frac{(\Theta_{C_t}^* - \Theta_{C_t}^{n_1})^2}{2\sigma^2}\right]} \end{aligned} \quad (12)$$

On the limit $\sigma^2 \rightarrow 0$, $\Theta_{C_t}^*$ is classified as class 0 if $\Theta_{C_t}^*$ has a point in the class 0 data which is closer than the closest point in the class 1 data. The nearest neighbor method is therefore recovered as the limiting case of a probabilistic generative model. The parameter k is chosen based on \sqrt{N} , where N is the number of samples in the training dataset. We refer the reader to [49,50] for a comprehensive treatment of the mathematical properties of k -nearest neighbors classifier.

3. Results

The annotated database introduced in Section 2.1 was used to compute the feature vector $[\zeta_t, \sigma_t^2, \tilde{x}_t] \in \mathbb{R}^3$, based on the statistical model of the coefficients of the continuous Morlet wavelet. The resulting features were used for off-line training the k -nearest neighbor classifier. With the 212 samples, k was set to 10 giving a 10-nearest neighbor.

Tables 2–4 show the statistical mean, standard deviation, variance and bounds values from the feature vector. One can note that, sigma (ζ_t), variance (σ_t^2), and median (\tilde{x}_t) are larger for SWD than for non-SWD. Therefore, despite the overlapping statistical bounds, a threshold can be determined to detect SWD patterns.

Table 2. Mean, standard deviation, variance and bound values for sigma parameter (ζ) for class 0 (non-spike-and-wave) and class 1 (spike-and-wave).

| | Mean | std | Variance | Bounds |
|---------|------|----------|----------|------------|
| Class 0 | 293 | 267.8017 | 71,718 | [12, 1275] |
| Class 1 | 542 | 406.2597 | 165,047 | [31, 1811] |

Table 3. Mean, standard deviation, variance and bound values for the variance (σ_t^2) for class 0 (non-spike-and-wave) and class 1 (spike-and-wave).

| | Mean | std | Variance | Bounds |
|---------|---------------------|---------------------|------------------------|--|
| Class 0 | 1.446×10^6 | 4.235×10^6 | 1.794×10^{13} | $[9.46 \times 10^2, 3.162 \times 10^7]$ |
| Class 1 | 4.32×10^6 | 7.892×10^6 | 6.228×10^{13} | $[2.715 \times 10^3, 4.321 \times 10^7]$ |

Table 4. Mean, standard deviation, variance and bound values for median (\tilde{x}_t) for class 0 (non-spike-and-wave) and class 1 (spike-and-wave).

| | Mean | std | Variance | Bounds |
|---------|----------------------|---------------------|---------------------|---|
| Class 0 | 1.089×10^3 | 1.002×10^4 | 1.004×10^8 | $[-2.769 \times 10^4, 2.179 \times 10^4]$ |
| Class 1 | -6.125×10^3 | 2.672×10^4 | 7.140×10^8 | $[-7.325 \times 10^4, 7.406 \times 10^4]$ |

To illustrate the above point, Figure 4 shows a 3D scatter plot of the feature vector for spike-and-wave events (SWD, class 1, red dots) and non-spike-and-wave events (non-SWD, class 0, blue dots). One observes that the SWD events tend to be more dispersed compared to non-SWD events. This is corroborated by Figure 5 that shows the parameters in pairs, with the following combinations

1. Scale parameter (ζ_t) vs. variance (σ_t^2): for class 1 (SWD), one observes a direct relationship between the variance and sigma, where both parameters grow proportionally. For class 0 (non-SWD), both sigma and variance remain in a limited range of values.
2. Scale parameter (ζ_t) vs. median (\tilde{x}_t): as sigma grows, median increases then decreases for both SWD and non-SWD, but is larger for SWD. A cone-shaped pattern can be observed.
3. Variance (σ_t^2) vs. median (\tilde{x}_t): as the variance grows, the median increases then decreases for SWD, while it remains in a small range (cluster) for non-SWD.

The performance of our 10-nearest neighbor classifier was evaluated using a dataset consisting of 96 samples, separate from the training set. These samples were extracted from six EEG signals from subjects different from those used for training. We assessed the total accuracy of the classification. The proposed method achieved a 95% sensitivity (true positive rate), 87% specificity (true negative rate), and 92% accuracy.

Figure 4. 3D scatter plot of the feature vector $[\zeta, \sigma_t^2, \tilde{x}_t]$ for class 0 (non-spike-and-waves events, blue dots), and class 1 (spike-and-waves events, red dots). The SWD events tend to be more dispersed than non-SWD events.

Figure 5. Scatter plots of the signals used for training, with ζ_t , σ_t^2 , and \tilde{x}_t parameters class 0 (non-spike-and-waves events, blue dots), and class 1 (spike-and-waves events, red dots), showing the data dispersion of the proposed approach. In (a) Scale parameter (ζ_t) vs. variance (σ_t^2). For class 1 (SWD), we can see the direct relationship between the variance and sigma, both grow proportionally, while for class 0 (non-SWD) both sigma and variance remain in a range of values. (b) Scale parameter (ζ_t) vs. median (\tilde{x}_t). As sigma grows, the median increases then decreases for both SWD and non-SWD, but is larger for SWD. (c) variance (σ_t^2) vs. median (\tilde{x}_t). As variance grows, the median increases then decreases for SWD, while it remains in a small range for non-SWD.

4. Discussion

The proposed model-based classification method to detect patient-specific spike-and-wave events in long-term EEG signals is based on three feature parameters (or predictors). These are the scale parameter from the generalized Gaussian distribution, see Equation (6), the variance and the median, all estimated from the continuous Morlet coefficients. These features are used with a 10-nearest neighbors classifier to discriminate spike-and-wave from non-spike-and-wave events. Experimental

results with real data from a hospital achieved 9 % sensitivity (true positive rate), 87% specificity (true negative rate), and 92% accuracy. Based on our rule to choose k , the value was $\sqrt{212} \approx 14$, but we found a better performance by choosing empirically $k = 10$. Techniques used in this study are widely known in the scientific community, but they have never before been put together to detect patient-specific epileptiform patterns in EEG. Our main contribution lies in the type of features proposed to detect spike-and-wave patterns and its application to human data. From a technical point of view, the GGD scale parameter depends on the shape parameter, see Equation (5) and Tables 2–4. They can therefore not be used together as features. Using only the scale parameter would restrict the representation space leading to poor representation of natural variability in the data. We, therefore, augmented the representation space by considering the variance and the median of wavelet coefficients. This choice has proven pertinent to discriminating SWD patterns from non-SWD.

The data collection protocol consisted of a neurologist selecting ten SWD patterns for each patient to be part of the training database. Our hypothesis was that using multiple signal patterns from individual patients improves the classification. This enhances learning patient-specific patterns, leading to precise detection of epileptiform patterns compared to previous work [39].

The collected dataset was previously used with other methods (see Table 5). We can see that the proposed method doesn't provide significantly more precise results. However, it has the advantage of analyzing the EEG signal in the time-frequency domain, where previous methods were based on temporal waveform characterization. On the other hand, the assumption that the data has a generalized Gaussian distribution allows a strong dimension reduction, leading to low computational solutions relying on rigorous statistical properties.

Table 5. Results from other methods applied to the same dataset in percent (%), in terms of TPR = True Positives Rate or Sensitivity; TNR = True Negative Rate or Specificity; FPR = False positive Rate; ACC = Accuracy; and high Specificity, rule in (SpPIn). Training and testing have different numbers of patients due to different research settings.

| Method | Features | Classifier | TPR | TNR | ACC | Training | Testing | Ref. |
|-----------------------------|--|----------------|-----|-----|-----|----------|---------|--------|
| GGD | GGD parameters, variance and median from time-frequency Morlet wavelet decomposition | 10-NN | 95 | 87 | 92 | 212 | 96 | Actual |
| Kendall's Tau-b Coefficient | Kendall's Tau-b coefficient significance in time domain | SpPIn | - | 94 | 94 | 300 | 300 | [39] |
| TLS | TLS parameters in time domain | 1-NN | 100 | 100 | 100 | 192 | 46 | [20] |

5. Conclusions

This paper presented a new model-based classification method to detect spike-and-wave events in long-term EEG signals in humans. The proposed method is based on the scale parameter of the generalized Gaussian distribution augmented with the variance and the median of the continuous Morlet wavelet coefficients from EEG data and a k -nearest neighbors classification technique.

The performance of the method was evaluated by training the model with an annotated real dataset containing 212 signal recordings consisting of spike-and-wave and non-spike-and-wave events. The classification performance was assessed by utilizing 96 segments and achieved 95% sensitivity (true positive rate), 87% specificity (true negative rate), and 92% accuracy. These results set the path to potentially new research to study the causes underlying the so-called *absence epilepsy* in long-term EEG recordings.

In addition to its performance, the proposed method can be implemented in online epilepsy care applications. However, due to the high dynamics of the EEG epileptic signals, some waveform might be incomplete (with part of the signal missing due to artifacts). Our method is not able to detect such situations, as confirmed by physicians using visual inspection [39]. Future work will focus on other

epileptic waveform patterns as well as on the extensive evaluation of the proposed approach and its comparison with other methods from the literature both in humans and rodents. Other techniques, such as visual data analysis with t-distributed stochastic neighbor embedding [51] and deep learning variational autoencoders [52] will be considered. For future clinical research, an on-line user interface will be implemented with different functionalities such as automatic SWD detection and SWD pattern counts for each brain region.

Author Contributions: conceptualization, A.Q.-R., V.M. and H.B.; formal analysis, A.Q.-R. and H.B.; investigation, A.Q.-R., V.M. and H.B.; methodology, A.Q.-R. and J.P.; software, A.Q.-R.; validation, A.Q.-R., V.M., C.D. and H.B.; visualization, A.Q.-R., V.M., C.D. and H.B.; writing—original draft, A.Q.-R. and J.P.; writing—review and editing, A.Q.-R., V.M., C.D., J.P. and H.B. All authors have read and agreed to the published version of the manuscript.

Funding: This research received no external funding.

Acknowledgments: Part of the work was conducted by AQR during his Ph.D. work at Buenos Aires Institute of Technology (ITBA). We would also like to thank the Bioengineering Ivana Zorgno for her assistance in the writing.

Conflicts of Interest: The authors declare no conflict of interest.

Abbreviations

The following abbreviations are used in this manuscript:

| | |
|---------|--|
| EEG | Electroencephalography |
| FLENI | Fight against Pediatric Neurological Disease |
| GGD | Generalized Gaussian distribution |
| k -NN | k -nearest neighbors |
| SWD | Spike-and-wave discharge |
